Capacity design (Ductility class DCM) of a light timber frame building

AUTORE: Mauro Andreolli, engineer

ABSTRACT

This work illlustrates the procedure for the capacity design of a light timber frame building in ductility class DCM. It also presents a practical application to a case study: a two-storey structure is designed using the software TimberTech Buildings, of which the calculation report is totally reproduced.

Dissipative structural behaviour

Earthquake-resistant timber buildings should be designed considering either:

- **dissipative structural behaviour;**
- **low-dissipative structural behaviour.**

In the first concept the capability of parts of the structure (dissipative zones) to resist earthquake actions out of their elastic range is taken into account. Dissipative zones shall be located in joints and connections, whereas the timber members themselves shall be regarded as behaving elastically.

In the second concept the action effects are calculated on the basis of an elastic global analysis without taking into account non-linear material behaviour.

Ductility classes and overstrength factor

Depending on their ductile behaviour and energy dissipation capacity under seismic actions, buildings shall be assigned to one of the three following ductility classes:

- **DCH, high capacity to dissipate energy;**
- **DCM, medium capacity to dissipate energy;**
- **DCL, low capacity to dissipate energy.**

In DCH and DCM the European standard (UNI EN 1998-1 §8.1.3) requires the use of the capacity design procedure. The capacity design has the purpose of ensuring a ductile behaviour to the dissipative structure and operates as follows:

- distinguishes elements and mechanisms, both local and global, into ductile and fragile;
- aims to avoid local brittle ruptures and the activation of global brittle or unstable mechanisms;
- aims at locating the energy dissipations by hysteresis in areas of the ductile elements identified and designed for this purpose.

To ensure the correct behaviour of the structure, the seismic resistance of the local/global brittle elements/mechanisms must be designed to be grater than that of the ductile elements/mechanisms. To ensure compliance with this inequality, both locally and globally, the strength of the ductile elements/mechanisms is increased by means of a suitable coefficient γ_{Rd} known as the “overstrength factor”; starting from this increased capacity, the capacity of the brittle elements/mechanisms is sized. This coefficient is defined as equal to 1.3 for the ductility class DCM and 1.6 for the ductility class DCH.

The resistance demand evaluated with the capacity design criteria can be assumed not to exceed the strength demand evaluated for the non-dissipative structural behaviour.

Dissipative zones and non-dissipative zones

Considering a light timber frame building in ductility class DCM, the dissipative zones consist of:

- mechanical connection between frame and cladding sheets;
- ductile elements of the traction connection (for example the nailing);
- ductile elements of the shear connection (for example the nailing).

The non-dissipative zones are instead represented by:

- cladding sheets;
- brittle elements of the traction connection (for example the concrete anchors);
- brittle elements of the shear connection (for example the concrete anchors);
- timber elements.

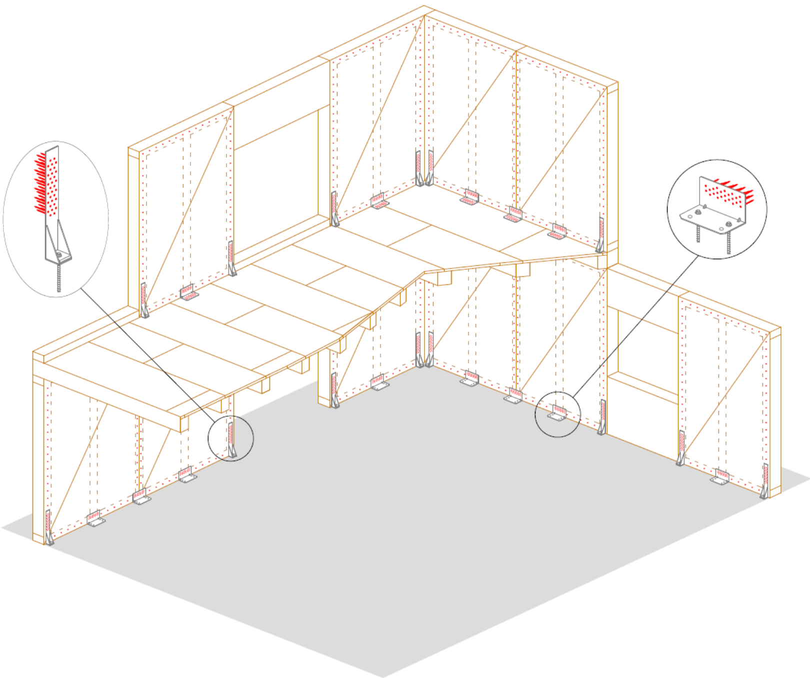

Figure 1 - *Light timber frame building in ductility class DCM: dissipative zones*

Calculation procedure

Applying capacity design locally and globally

Planning according to capacity design procedures is therefore divided into two application "levels":

- **local level, related to the connection of the structure;**
- **global level, related to the walls and the building.**

The first has the purpose of avoiding the prevalence of brittle failure modes in dissipative connections. The second instead provides for the application of a series of rules aimed at avoiding non-dissipative collapse mechanisms and fragile breakages of the elements that make up the structure.

Calculation of design resistances

The design strength of the dissipative zones is defined by the following formula:

$$F_{Rd,ductile} = k_{R,deg} \cdot k_{mod} \cdot \frac{F_{Rk,ductile}}{\gamma_M}$$

where:

$F_{Rd,ductile}$ is the design value of the strength of the dissipative zones;

$k_{R,deg}$ is the strength reduction factor due to cyclic degradation;

k_{mod} is the modification factor for duration of load and moisture content;

$F_{Rk,ductile}$ is the characteristic value of the strength of the dissipative zones;

γ_M is the material partial factor.

The design resistance of the non-dissipative zones is defined by the following formula:

$$F_{Rd,brittle} = k_{mod} \cdot \frac{F_{Rk,brittle}}{\gamma_M}$$

where:

$F_{Rd,brittle}$ is the design value of the strength of the non-dissipative zones;

k_{mod} is the modification factor for duration of load and moisture content;

$F_{Rk,brittle}$ is the characteristic value of the strength of the non-dissipative zones;

γ_M is the material partial factor.

Evaluation of the degradation of strength due to seismic actions

First of all, the strength of materials can be reduced to take into account the degradation due to cyclic deformations.

The designer can therefor proceed by following two paths:

- if precise information is not available regarding the possible degradation of the strength of the materials due to cyclic deformations, it can apply the values of the partial safety coefficients on the materials adopted for the fundamental design situations;
- if, on the other hand, the degradation of strength is appropriately taken into account in the evaluation of the mechanical properties of materials, then it is possible to use the safety coefficients corresponding to accidental load combinations.

So the question is, what is the value of the strength degradation factor due to the effect of cyclic actions, indicated above with $k_{R,deg}$?

With reference to the specific case of timber structures, for ultimate limit state verifications of structures designed in accordance with the concept of dissipative behaviour, it is possible to assume the partial safety factors for the accidental load combinations taking into account the cycle degradation through a maximum 20% reduction of the resistance, which means that the coefficient $k_{R,deg}$ is equal to 0,8.

Checks

Check dissipative zones

The dissipative zones against the seismic actions calculated with the dissipative behavior factor need to be verified according to the following expression:

$$F_{Ed,ductile} \leq F_{Rd,ductile} = k_{R,deg} \cdot k_{mod} \cdot \frac{F_{Rk,ductile}}{\gamma_M}$$

where:

$F_{Ed,ductile}$	is the design value of the effect of actions of the dissipative zones;
$F_{Rd,ductile}$	is the design value of the strength of the dissipative zones;
$F_{Rk,ductile}$	is the characteristic value of the strength of the dissipative zones;
$k_{R,deg}$	is the strength reduction factor due to cyclic degradation;
k_{mod}	is the modification factor for duration of load and moisture content;
γ_M	is the material partial factor.

Check non-dissipative zones – Local level

In order to ensure compliance with the rules of capacity design at the local level (connection), it must be verified that the resistances associated with the brittle failure modes are over-resistant compared to the resistance associated with the ductile failure mode:

$$F_{Rd,brittle} \geq \frac{\gamma_{Rd}}{k_{R,deg}} \cdot F_{Rd,ductile}$$

where:

γ_{Rd}	is the overstrength factor;
$k_{R,deg}$	is the resistance degradation coefficient due to cyclic actions;
$F_{Rd,ductile}$	is the design value of the strength of the dissipative zones;
$F_{Rd,brittle}$	is the design value of the strength of the non-dissipative zones.

Check non-dissipative zones – Global level

The non-dissipative zones need to be checked towards the actions deriving from the application of the capacity design rules. The design effect of the actions is obtained through the following relationship:

$$F_{Ed,brittle} = \Omega \cdot F_{Ed,brittle,E} + F_{Ed,brittle,G}$$

where:

$F_{Ed,brittle}$	is the design action effect in the non-dissipative connection or member;
Ω	is the structure overstrength ratio (in both x and y directions);

$F_{Ed,brittle,E}$ is the action effect in the non-dissipative connection or member of the design seismic action;

$F_{Ed,brittle,G}$ is the action effect in the non-dissipative connection or member of the non-seismic actions in the design seismic situation.

The overstrength ratio for each floor of the building and for each direction is determined by the following expression:

$$\Omega_{i,j} = min\left\{\frac{\sum_{k=1}^{N_{i,j}} V_{Rd,i,j,k}^{sh,CD}}{\sum_{k=1}^{N_{i,j}} \left|V_{Ed,i,j,k}\right|}; \frac{\sum_{k=1}^{N_{i,j}} V_{Rd,i,j,k}^{ang,CD}}{\sum_{k=1}^{N_{i,j}} \left|V_{Ed,i,j,k}\right|}; \frac{\sum_{k=1}^{N_{i,j}} M_{Rd,i,j,k}^{hd,CD}}{\sum_{k=1}^{N_{i,j}} \left|M_{Ed,i,j,k}\right|}\right\}$$

where:

$\sum_{k=1}^{N_{i,j}} V_{Rd,i,j,k}^{sh,CD}$ is the sum of the design lateral strength related to connections between cladding sheet and timber frame of the j-th shear wall at the i-th storey, taking into account the overstrength factor through the ratio $\gamma_{Rd}/k_{R,deg}$;

$\sum_{k=1}^{N_{i,j}} V_{Rd,i,j,k}^{ang,CD}$ is the sum of the design lateral strength related to shear connections of the j-th shear wall at the i-th storey, taking into account the overstrength factor through the ratio $\gamma_{Rd}/k_{R,deg}$;

$\sum_{k=1}^{N_{i,j}} M_{Rd,i,j,k}^{hd,CD}$ is the sum of the design rocking strength of the j-th shear wall at the i-th storey, taking into account the overstrength factor through the ratio $\gamma_{Rd}/k_{R,deg}$;

$\sum_{k=1}^{N_{i,j}} \left|V_{Ed,i,j,k}\right|$ is the sum of the absolute values of the design global shear of the j-th shear wall at the i-th storey due to the seismic action;

$\sum_{k=1}^{N_{i,j}} \left|M_{Ed,i,j,k}\right|$ is the sum of the absolute values of the design rocking moment of the jth shear wall at the ith storey due to the seismic action;

$N_{i,j}$ is the number of shear-walls parallel to the seismic action at the i-th storey.

Case study

The analyzed building, used for residential purpose, has two floors above ground with a maximum height at the ridge of 7.45 m and a rectangular plan measuring 10 x 11 m. It is a structure that has an almost symmetrical distribution of the walls in plan and it is regular both in plan and in height.

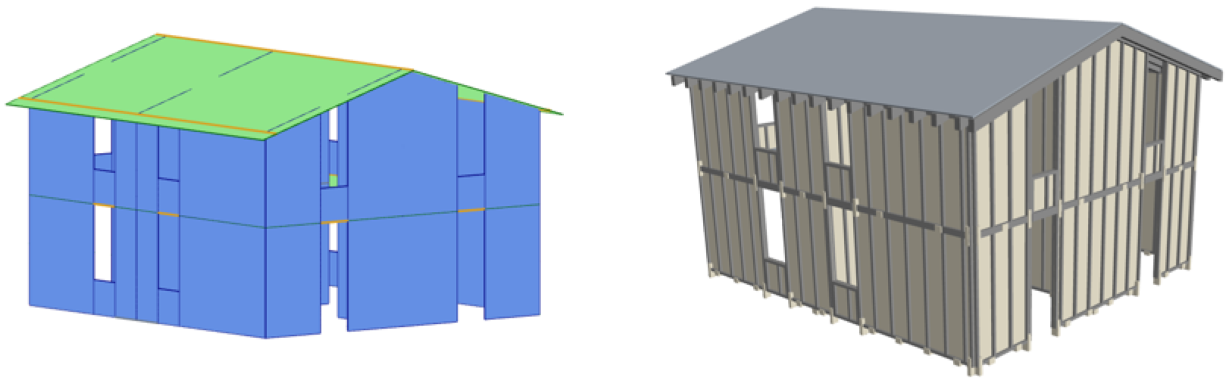

Figure 2 – *TimberTech Buildings model for the case study*

The bearing structure is made up of light framed walls with 12 mm thick OSB/3 as cludding sheets fixed to the timber frame by means of 2.8/3.1x60 mm high bond nails. The post and crossbeam of the frame are in class C24 solid wood and have 80x160 mm sections.

Attached is the complete calculation report generated using the TimberTech Buildings software, where all the verifications of the structure are present, including the application of capacity design.

Materials

Wooden materials

The materials used in the project are listed in the following tables.

Descr.	Description
$f_{m,k}$	Characteristic bending strength
$f_{t,0,k}$	Characteristic tensile strength along the grain
$f_{t,90,k}$	Characteristic tensile strength perpendicular to the grain
$f_{c,0,k}$	Characteristic compressive strength along the grain
$f_{c,90,k}$	Characteristic compressive strength perpendicular to the grain
$f_{v,k}$	Characteristic shear strength
$E_{0,mean}$	Mean value of modulus of elasticity along the grain
$E_{0,05}$	Fifth percentile value of modulus of elasticity along the grain
$E_{90,mean}$	Mean value of modulus of elasticity perpendicular to the grain
G_{mean}	Mean value of shear modulus
ρ_k	Characteristic density

Calculation method and numerical model

Model Description

Hypothesis adopted for the elements

The timber walls are constrained at the base by means of connection systems capable of transmitting both in-plane and out-of-plane actions action on the wall.

In the analysis, in presence of horizontal loads, some elements may be defined as “secondary”: this mean that their strength and stiffness are neglected in the calculation of the response of the building. In the model these elements are represented in terms of mass and they are designed only for vertical loads.

Rigid body rocking – Forces on hold-down / tie-down

The hold-down or tie-down systems are used to prevent the rotation of the wall caused by the overturning moment of the horizontal force. The hold-down, placed on the in-tension edge of the wall, is loaded by a force equal to

$$T = \begin{cases} \left(\dfrac{M_{3-3}}{b} - \dfrac{N}{2}\right) \cdot \dfrac{1}{n_{anc}} & for\ active\ hold-down \\ 0 & for\ inactive\ hold-down \end{cases}$$

where:

b is the lever arm for the internal couple;

N is the axial vertical load acting on the wall;

M_{3-3} is the moment acting in the plane of the wall;

n_{anc} is the number of connections present at each end of the wall.

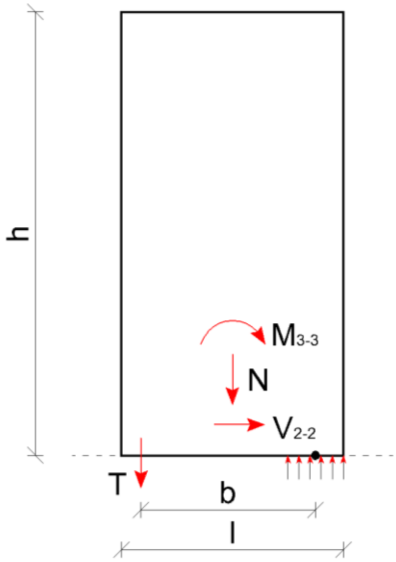

Figure: Calculation model of tensile force acting on the hold-down

Structural elements

The following table shows the positions of the individual walls. The last four columns show the coordinates of the ends of each wall.

X1 and Y1 indicate the coordinates of the starting point of the wall

X2 and Y2 indicate the coordinates of the end point of the wall

Wall horizontal stiffness

The wall stiffness can be estimated considering the contributions of all the components, as shown below.

Timber framed shear walls

In the case of framed walls the overall stiffness is calculated taking into account the contribution of the following components:

- sheeting boards (k_s)
- sheet-fasteners slip (k_c)
- shear connections – angle brackets (k_a)
- hold-down or tie-down (k_h)

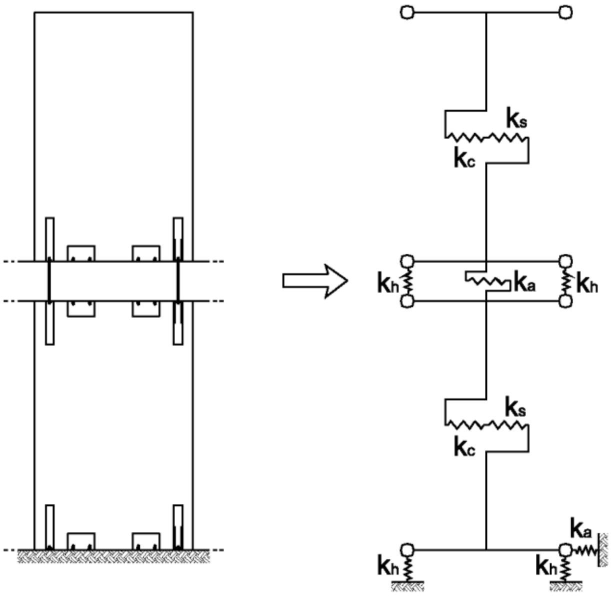

Figure: Mechanical model for framed walls overall stiffness

Types of structural elements and sign conventions

Linear elements

The linear elements are used to model beams and columns. They have a local reference system with respect to which stress/force components are shown. The sign convention adopted is shown in the figure below.

Force	Description	Unit of measure
N	Axial force	kN
M_{3-3}	Bending moment about local axis 3	kN m
V_2	Shear along local axis 2	kN
M_{2-2}	Bending moment about local axis 2	kN m
V_3	Shear along local axis 3	kN

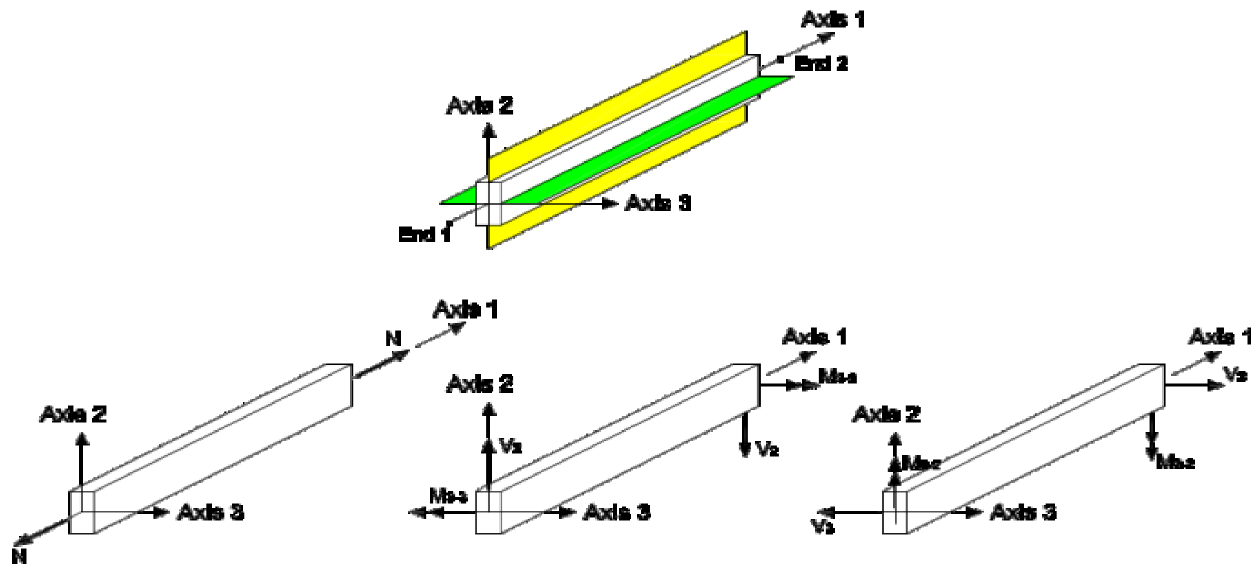

Figure: sign conventions for beams

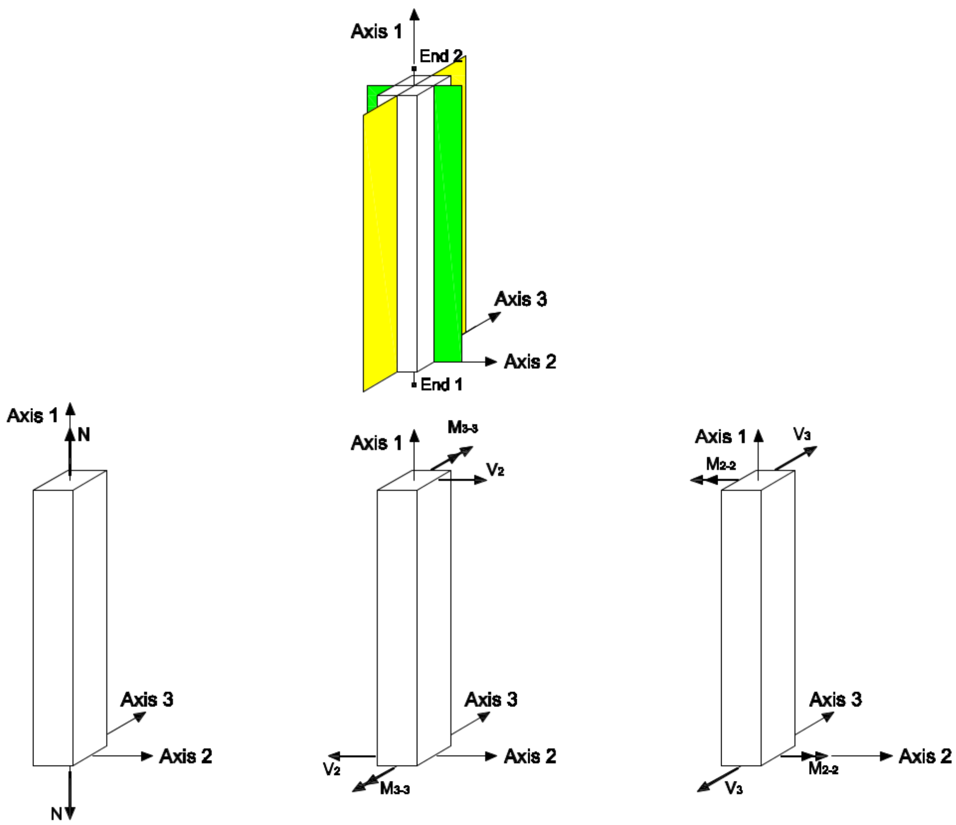

Figure: sign conventions for columns

Wall elements

The walls, regardless of type, have the following sign conventions.

	Actions per unit length	Description	Unit of measure
In-plane actions	n	Axial stress (per unit length)	kN/m
	m_{3-3}	Bending moment about local axis 3 (per unit length)	kNm/m
	v_2	Shear along local axis 2 (per unit length)	kN/m
Out-of-plane actions (plate)	m_{2-2}	Bending moment about local axis 2 (per unit length)	kNm/m
	v_3	Shear along local axis 3 (per unit length)	kN/m

	Actions	Description	Unit of measure
In-plane actions	N	Total axial force	kN
	M_{3-3}	Bending moment about local axis 3	kNm
	V_2	Shear along local axis 2	kN
Out-of-plane actions (plate)	M_{2-2}	Bending moment about local axis 3	kNm
	V_3	Shear along local axis 2	kN

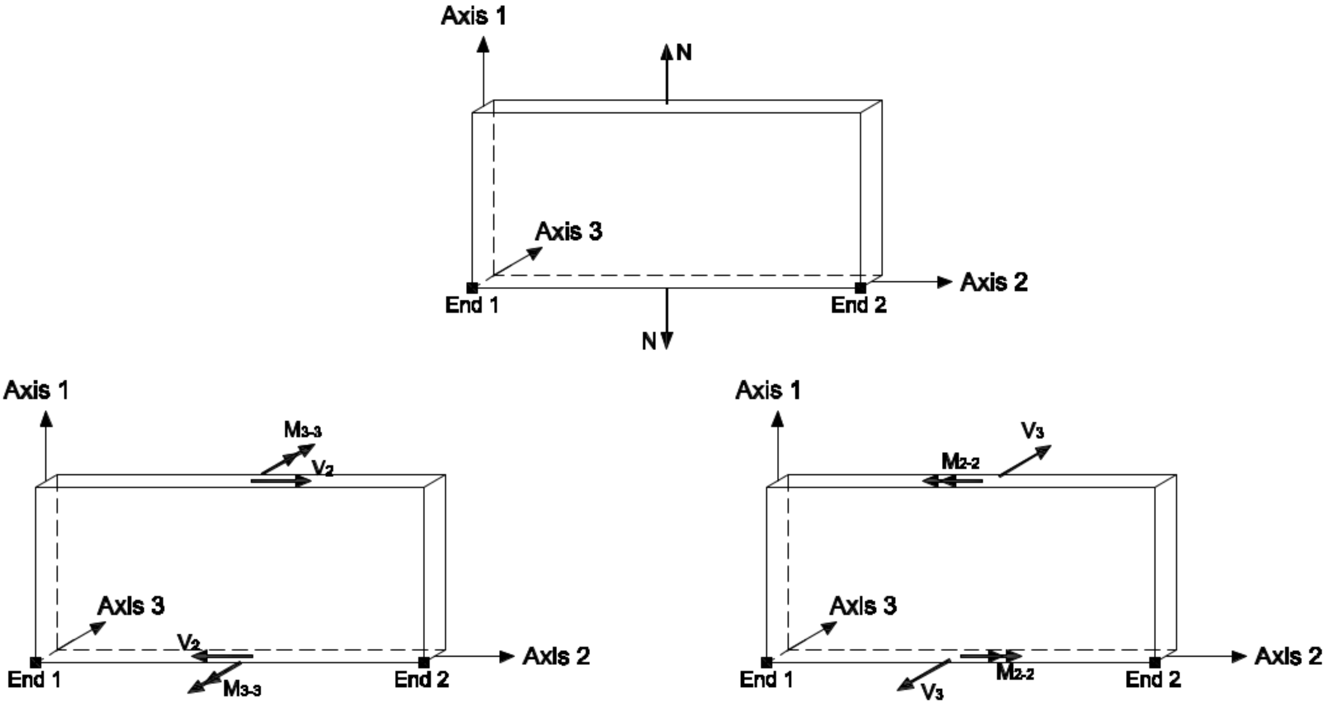

Figure: sign conventions for walls

Actions and design loads

Self-weight of structural materials

The weights of the structural materials are shown in the table below in kN/m^3

Description	Specific weight γ [kN/m^3]
GL 24h - EN 14080	5
C 24	5
OSB/3	8

Wind action

The wind action is evaluated in accordance with the European standard EN 1-1-4. The wind action is represented by a simplified set of forces whose effects is equivalent to the extreme effects of the turbulent wind.

Project data

Terrain category: Terrain category 0

Basic wind velocity: 27 m/s

Mean wind

The mean wind velocity $v_m(z)$ at a height z above the terrain depends on the terrain roughness and orography and on the basic wind velocity according to the following expression:

$$v_m(z) = c_r(z) \cdot c_o(z) \cdot v_b$$

where:

$c_r(z)$ is the roughness factor that depends on the terrain category and on the height z above the terrain of the relevant point;

$c_o(z)$ is the orography factor taken as 1;

v_b is the basic wind velocity.

According to section 4.3.2 of EN 1991-1-4, the roughness factor can be determined as follows:

$$c_r(z) = k_r \cdot \ln\left(\frac{z}{z_0}\right) \quad for \quad z_{min} \leq z \leq z_{max}$$
$$c_r(z) = c_r(z_{min}) \quad for \quad z \leq z_{min}$$

where:

z_0 and z_{min} are defined according to the terrain category:

	Terrain category	z_0	z_{min}
0	Sea or coastal area exposed to the open sea	0,003	1
I	Lakes or flat and horizontal area with negligible vegetation and without obstacles	0,01	1
II	Area with low vegetation such as grass and isolated obstacles (trees, buildings) with separations of at least 20 obstacle heights	0,05	2
III	Area with regular cover of vegetation or buildings or with isolated obstacles with separations of maximum 20 obstacle heights (such as villages, suburban terrain, permanent forest)	0,3	5
IV	Area in which at least 15% of the surface is covered with buildings and their average height exceeds 15 m	1,0	10

k_r is the terrain factor calculated using:

$$k_r = 0{,}19 \cdot \left(\frac{z_0}{z_{0,II}}\right)^{0{,}07}$$

with: $z_{0,II} = 0{,}05\ m$

Wind turbulence

The turbulence intensity $I_v(z)$ at a height z is defined as the standard deviation of the turbulence divided by the mean wind velocity and it can be determined as:

$$I_v(z) = \frac{\sigma_v}{v_m(z)} = \frac{1}{c_o(z) \cdot \ln\left(\frac{z}{z_0}\right)} \quad for \quad z_{min} \le z \le z_{max}$$

$$I_v(z) = I_v(z_{min}) \qquad for \qquad z \le z_{min}$$

Peak velocity pressure

The peak velocity pressure $q_p(z)$ at a height z can be determined as:

$$q_p(z) = [1 + 7 \cdot I_v(z)] \cdot \frac{1}{2} \cdot \rho \cdot v_m^2(z) = c_e(z) \cdot q_b$$

where:

$I_v(z)$ is the turbulence intensity;

ρ is the air density taken as 1.25 kg/m^3;

$v_m(z)$ is the mean wind velocity;

$c_e(z)$ is the exposure factor defined as $c_e(z) = \frac{q_p(z)}{q_b}$;

q_b is the basic wind pressure defined as $q_b = \frac{1}{2} \cdot \rho \cdot v_b^2$.

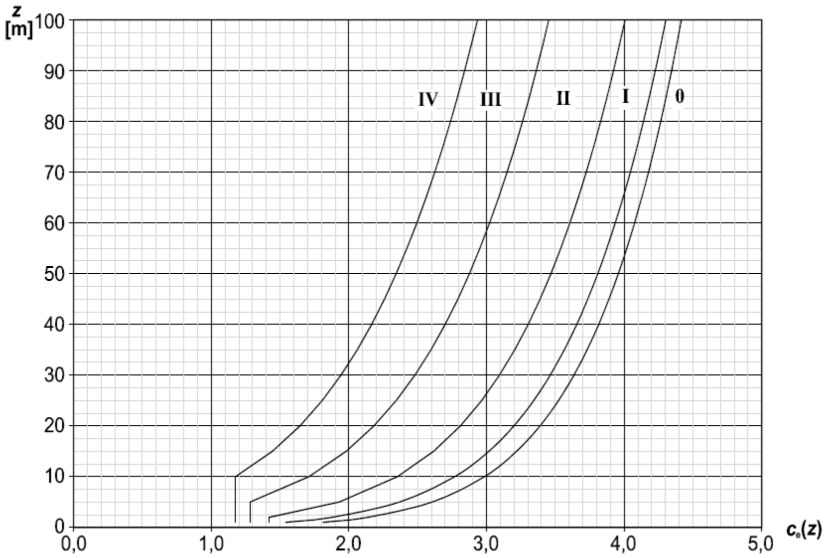

Figure 4.2 — Illustrations of the exposure factor $c_e(z)$ for c_O=1,0, k_l=1,0

The basic wind pressure results to be equal to:

q_b 455.63 N/m^2

Wind pressure on surfaces

The wind pressure acting on the external surfaces can be determined according to:

$$w_e(z_e) = q_p(z_e) \cdot c_{pe}$$

The wind pressure acting on the internal surfaces can be determined according to:

$$w_i(z_i) = q_p(z_i) \cdot c_{pi}$$

where:

c_{pe} is the pressure coefficient for the external pressure that can be calculated according to section 7.2 of EN 1991-1-4 or according to data supported by appropriate documentation or by experimental campaigns in wind tunnel;

c_{pi} is the pressure coefficient for the internal pressure.

The reference heights z_e to be considered in the calculation of the peak reference wind pressure are defined as follows:

- Windward surfaces of walls: the reference height changes along the structure height in accordance with point 7.2.2 on EN 1991-1-4;
- Leeward surfaces of walls: the reference height is equal to the maximum height of the building;
- Internal pressures: the reference height is equal to the maximum height of the building.

Wind forces

The wind forces for the whole structure or a structural component can be determined by calculating forces from surface pressures according to the following equations.

External forces:

$$F_{w,e} = c_s \cdot c_d \cdot \sum_{surfaces} w_e(z_e) \cdot A_{ref}$$

Internal forces:

$$F_{w,i} = \sum_{surfaces} w_i(z_i) \cdot A_{ref}$$

where:

c_s is the size factor that takes into account the effect on wind actions from the non-simultaneous occurrence of peak wind pressures on the surfaces. It is taken equal to 1;

c_d is the dynamic factor that takes into the effect of the vibrations of the structure due to turbulence. It is taken equal to 1.

Loads acting on the walls

The following table shows the loads acting on the walls.

Load name: Load ID

Position: Position of the wall: internal or external

$g_{1,k}$: Permanent action: self weight

$g_{2,k}$: Permanent action

$q_{,wind,k}$: Variable actions: wind load on windward, leeward and lateral surfaces

Wall name	Position	Load name	$g_{1,k}$ [kN/m^2]	$g_{2,k}$ [kN/m^2]	$q_{,wind,k}$ downwind [kN/m^2]	$q_{,wind,k}$ windward [kN/m^2]	$q_{,wind,k}$ lateral [kN/m^2]

Seismic actions

The seismic actions are evaluated according to the Eurocode 8 and the National annex. The earthquake motion at a given point on the surface is represented by an elastic ground acceleration response spectrum.

The response spectra are calculated using the design ground acceleration a_g on type A ground: the acceleration is equal to a_{gR}, the value of the reference peak ground acceleration on type A ground, times the importance factor γ_I.

The response spectrum for the damage limit requirement is obtained multiplying the reduction of the design ground acceleration a_g by the reduction factor ν.

The parameters defining the design ground acceleration a_g on type A ground and the acceleration values for the ULS and DLS are reported below:

The reduction factor of the Damage limitation Limit State spectrum: 0.5

Importance factor: 1

Limit States	a_g[g]
ULS – Ultimate Limit State	0.261
DLS – Damage Limitation limit State	0.131

The value of the periods T_B, T_C, T_D and of the soil factor S defining the shape of the elastic response spectrum depend on the ground type and on the spectrum type. The parameters used are reported below:

Spectrum type: Type 1

Ground type: A

S soil factor: 1

T_B lower limit of the period of the constant spectral acceleration branch: 0.15 s

T_C upper limit of the period of the constant spectral acceleration branch: 0.4 s

T_D value defining the beginning of the constant displacement response range of the spectrum: 2 s

Horizontal elastic response spectrum

For the horizontal components of the seismic action, the elastic response spectrum $S_e(T)$ *is defined by the following expressions:*

$0 \leq T \leq T_B$ $\quad S_e(T) = a_g \times S \times \left[1 + \frac{T}{T_B} \times (\eta \times 2{,}5 - 1)\right]$

$T_B \leq T \leq T_C$ $\quad S_e(T) = a_g \times S \times \eta \times 2{,}5$

$T_C \leq T \leq T_D$ $\quad S_e(T) = a_g \times S \times \eta \times 2{,}5 \left[\frac{T_C}{T}\right]$

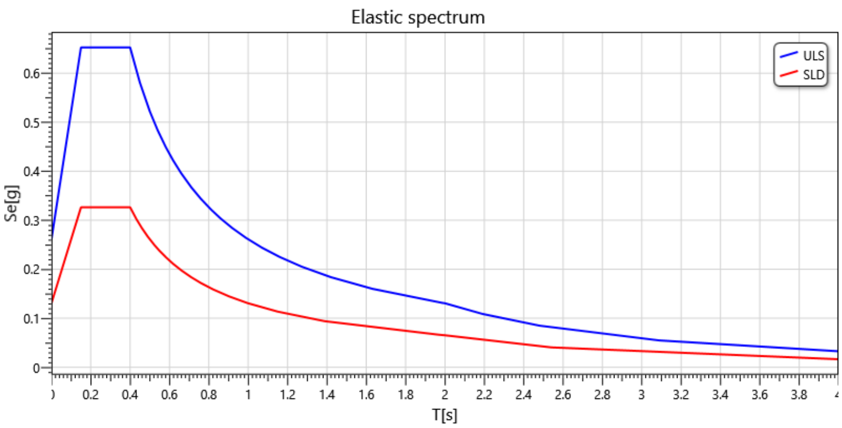
$T \leq T_D$ $\quad S_e(T) = a_g \times S \times \eta \times 2{,}5 \left[\frac{T_C T_D}{T^2}\right]$

Horizontal elastic response spectra are reported below; they are calculated using the following values of the parameters η and ξ

η 1

ξ 5%

η is the damping correction factor with a reference value of η = 1 for 5% viscous damping.



Design spectrum for elastic analysis (NO-COLLAPSE)

To avoid explicit inelastic structural analysis in design, the capacity of the structure to dissipate energy, through mainly ductile behavior of its elements and/or other mechanisms, is taken into account by performing an elastic analysis based on a response spectrum reduced with respect to the elastic one, henceforth called a "design spectrum". This reduction is accomplished by introducing the behavior factor q. The design spectrum is *defined by the following expressions:*

$0 \leq T \leq T_B$ $\quad S_d(T) = a_g \times S \times \left[\frac{2}{3} + \frac{T}{T_B} \times \left(\frac{2{,}5}{q} - \frac{2}{3}\right)\right]$

$T_B \leq T \leq T_C$ $\quad S_d(T) = a_g \times S \times \frac{2{,}5}{q}$

$T_C \leq T \leq T_D$ $\quad S_d(T) = \begin{cases} a_g \times S \times \frac{2{,}5}{q} \times \left[\frac{T_C}{T}\right] \\ \geq \beta \times a_g \end{cases}$

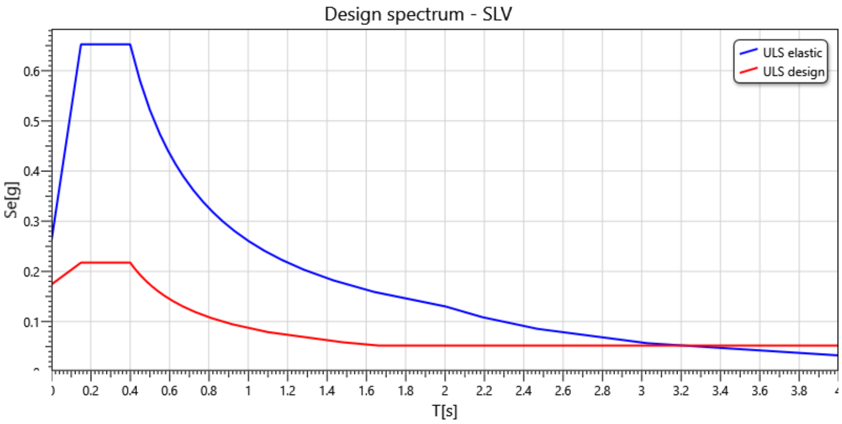
$T \leq T_D$ $\quad S_d(T) = \begin{cases} a_g \times S \times \frac{2{,}5}{q} \times \left[\frac{T_C T_D}{T^2}\right] \\ \geq \beta \times a_g \end{cases}$

where:

β is the lower bound factor for the horizontal design spectrum equal to 0.2;

q is the behaviour factor: 3.

The horizontal elastic response spectra and the horizontal design spectrum (Ultimate Limit State) are shown below:



Sections of the structural elements

Combinations of actions

For each critical load case, the design values of the effects of actions shall be determined by combining the values of actions that are considered to occur simultaneously.

$$\sum_{j\geq 1} \gamma_{G,j} G_{k,j} + \gamma_{Q,1} Q_{k,1} + \sum_{i\geq 1} \gamma_{Q,i} \psi_{0,\mathrm{i}} Q_{k,i} =$$

$$= \gamma_{G1} \cdot G_1 + \gamma_{G2} \cdot G_2 + \gamma_Q \cdot Q_{k1} + \gamma_{Q2} \cdot \psi_{02} \cdot Q_{k2} + \gamma_{Q3} \cdot \psi_{03} \cdot Q_{k3} + \cdots$$

Combinations of actions for seismic design situations:

$$\sum_{j\geq 1} G_{k,j} + A_{Ed} + \sum_{i\geq 1} \psi_{2,\mathrm{i}} Q_{k,i} =$$

$$= G_1 + G_2 + A_{Ed} + \psi_{21} \cdot Q_{k1} + \psi_{22} \cdot Q_{k2} + \cdots$$

being:

G_1 permanent actions: self weight;

G_2 permanent actions;

Q_1 characteristic value of the main variable action;

Q_{ki} characteristic value of the i-th variable action;

γ_{G1} is the partial factor for the self-weight action;

γ_{G2} is the partial factor for the permanent actions action.

When permanent actions, as well as a portion of those, are fully defined in design process, it is possible to adopt the same partial factor employed for self-weight actions.

The following are the values of the combination coefficients used.

Action name	Description	Duration	ψ_0	ψ_1	ψ_2
Q cat.A	Category A: domestic, residential areas	Medium-term	0.7	0.5	0.3
Q cat.B	Category B: office areas	Medium-term	0.7	0.5	0.3

Combinations of actions used

Vertical ULS loads combinations

The following table shows the ULS load combinations relevant for verifications in conditions of vertical load. The coefficient values listed correspond to the product of the partial safety factor γ_j and the combination factors ψ_{0j}.

The action of the wind is schematized with a uniform load orthogonal to each external wall.

Horizontal ULS loads combinations

The following table shows the ULS load combinations relevant for verifications in conditions of vertical load. The coefficient values listed correspond to the product of the partial safety factor γ_j and the combination factors ψ_{0j}.

The action of the wind is schematized with a uniform load orthogonal to each external wall and it acts separately in the directions x, -x, y, -y.

Seismic load combinations

The action effects due to the combination of the horizontal components of the seismic action are computed using the following combinations:

$$E_{Edx} + 0{,}3 \cdot E_{Edy}$$

$$0{,}3 \cdot E_{Edx} + E_{Edy}$$

Horizontal actions

Modal analysis

The modal analysis is used to determine the vibration modes of the structure, useful to understand the seismic behaviour of the building and to proceed with the linear dynamic analysis.

The modal analysis involves the solution of the generalized eigenvalue problem:

$$[\boldsymbol{K} - \boldsymbol{\Omega}^2 \boldsymbol{M}]\boldsymbol{\Phi} = \boldsymbol{0}$$

where $\boldsymbol{K}$ is the stiffness matrix, $\boldsymbol{M}$ the mass matrix, $\boldsymbol{\Omega}^2$ is the diagonal matrix of the eigenvalues and $\boldsymbol{\Phi}$ is the corresponding matrix of eigenvectors or modal shapes (normalized with respect to the mass matrix); the seismic masses of the diaphragms are calculated with the following combination of vertical loads:

$$\sum G_{k,j} + \sum \psi_{\mathrm{Ei}} \cdot \mathrm{Q_{ki}} = \mathrm{G_1} + \mathrm{G_2} + \sum \psi_{\mathrm{Ei}} \cdot \mathrm{Q_{ki}}$$

where ψ_{Ei} is the combination coefficient for variable action *i.* The combination coefficients shall be computed from the following expression:

$$\psi_{\mathrm{Ei}} = \varphi \cdot \psi_{\mathrm{2i}}$$

Type of variable action	Storey	φ
Categories A-C (as defined in EN 1991-1-1)	Roof Storeys with correlated occupancies Independently occupied storeys	1 0.8 0.5

The base shear forces for DLS and ULS and the respective acceleration values are given below.

The eigenvalue, obtained by the solution of the generalized eigenvalue problem, is the square of the circular frequency $\boldsymbol{\omega}$ related to the period, *T*, and to the frequency, *f*, by the following equations:

$$T = \frac{1}{f} \text{ and } f = \frac{\omega}{2\pi}$$

The participating mass ratio for the mode *i-th*, corresponding to an acceleration in the global axis X and Y and to a rotational acceleration around the vertical axis Z, is given by:

$$M_x^i = \frac{m_x^i}{\sum m_{x,j}} \ [\%]$$

$$M_y^i = \frac{m_y^i}{\sum m_{y,j}} \ [\%]$$

$$M_z^i = \frac{m_z^i}{\sum I_{z,j}} \; [\%]$$

where:

$$m_x^i = \frac{\left([\boldsymbol{\Phi}^i]^T \boldsymbol{M}\, \boldsymbol{R}_x\right)^2}{[\boldsymbol{\Phi}^i]^T \boldsymbol{M}\, \boldsymbol{\Phi}^i}$$

$$m_y^i = \frac{\left([\boldsymbol{\Phi}^i]^T \boldsymbol{M}\, \boldsymbol{R}_y\right)^2}{[\boldsymbol{\Phi}^i]^T \boldsymbol{M}\, \boldsymbol{\Phi}^i}$$

$$m_z^i = \frac{\left([\boldsymbol{\Phi}^i]^T \boldsymbol{M}\, \boldsymbol{R}_z\right)^2}{[\boldsymbol{\Phi}^i]^T \boldsymbol{M}\, \boldsymbol{\Phi}^i}$$

and where $\sum m_{x,j}$, $\sum m_{y,j}$ and $\sum I_{z,j}$ are the total masses acting in the axis X, Y and the total rotational inertia about the axis Z of the unrestrained *j-th* degrees of freedom.

Mode	Period [s]	Frequency [Hz]	M_X [%]	Sum M_X [%]	M_Y [%]	Sum M_Y [%]	M_Z [%]	Sum M_Z [%]
Mode 1	0.29	3.43	89.41	89.41	0.09	0.09	0.49	0.49

Mode 6	0.10	10.26	0.04	100.00	0.01	100.00	8.19	100.00

The table shows, limited to the first six modes of vibration, the corresponding period and the modal deformed shape.

Mode	Period [s]	Modal deformed shape
Mode 1	0.29	
Mode 2	0.29	Mode 3	0.22	
Mode 4	0.13	Mode 5	0.13	
Mode 6	0.10	
Dynamic linear analysis

The dynamic linear analysis consists of:

- the calculation of the seismic effects (the seismic action is represented by the design response spectrum), of each of the vibration modes calculated in the modal analysis;
- combination of these effects.

The seismic effects of the structural model are obtained by the application of the following external loads:

$$\boldsymbol{F_x^i} = \Gamma_x^i S_d(T_i)\boldsymbol{M\Phi^i}$$

and

$$\boldsymbol{F_y^i} = \Gamma_y^i S_d(T_i)\boldsymbol{M\Phi^i}$$

where:

$\boldsymbol{F_x^i}$ and $\boldsymbol{F_y^i}$ are the external loads of the *i-th vibration mode* due to seismic action along X and Y;

$\boldsymbol{S_d}(\boldsymbol{T_i})$ is the spectrum value corresponding to the *i-th* period;

$\boldsymbol{\Phi^i}$ is the *i-th modal shape;*

Γ_x^i and Γ_y^i are the participating modal factor of the *i-th mode* given by:

$$\Gamma_x^i = \frac{[\boldsymbol{\Phi^i}]^{\boldsymbol{T}}\boldsymbol{M}\,\boldsymbol{R_x}}{[\boldsymbol{\Phi^i}]^{\boldsymbol{T}}\boldsymbol{M}\,\boldsymbol{\Phi^i}}\ and\ \Gamma_y^i = \frac{[\boldsymbol{\Phi^i}]^{\boldsymbol{T}}\boldsymbol{M}\,\boldsymbol{R_y}}{[\boldsymbol{\Phi^i}]^{\boldsymbol{T}}\boldsymbol{M}\,\boldsymbol{\Phi^i}}$$

The effects for a given direction of acceleration (along X or Y) and for each of the vibration modes are combined with the Complete Quadratic Combination technique defined as:

$$E = \left(\sum_j \sum_i \rho_{ij} \cdot E_i \cdot E_j\right)^{1/2}$$

where:

E_j is the effect of the j-th vibration mode;

ρ_{ij} is the correlation coefficient of the *i-th* mode and the *j-th* mode, given by:

$$\rho_{ij} = \frac{8\,\xi^2\beta_{ij}^{3/2}}{(1+\beta_{ij})\big[(1-\beta_{ij})\big]}$$

ξ is the damping ratio in the i-th and j-th modes;

$\beta_{ij} = T_j/T_i)$.

The following table provides the diaphragms properties.

Diaphragm	Height above the base of the timber structure [m]	xG [m]	yG [m]	Accidental eccentricity ex [m]	Accidental eccentricity ey [m]	Mass i [kg]
1	3.20	5.00	5.61	0.50	0.55	36843
2	6.63	5.00	5.61	0.55	0.60	24232

The following table provides, for each of the vibration mode, the corresponding period and value of the response spectrum, both SLV value and the SLD value.

Mode	Period [s]	SLV spectrum value [g]	SLD spectrum value [g]
Mode 1	0.30	0.22	0.33
Mode 2	0.29	0.22	0.33
Mode 3	0.21	0.22	0.33
Mode 4	0.14	0.21	0.31
Mode 5	0.13	0.21	0.30
Mode 6	0.10	0.20	0.25

Wind

The table below illustrates the horizontal forces acting on the storeys due to the wind action and the coordinates of their respective application points.

Diaphragm	Height above the reference plane [m]	xG,wind [m]	yG,wind [m]	Fx [kN]	Fy [kN]
1	3.20	5.00	5.50	47.42	42.24
2	6.63	5.00	5.50	29.31	26.23

The action effects

In this chapter are reported the internal stresses present in the structural elements and their connections caused by the different loads.

Walls

Forces and moments acting at the base of the structure

In this chapter are reported the values of actions acting at the base of the walls and columns of the ground floor. With regard to the walls the first row of the table shows the values of the actions related to the ULS combination that maximizes the axial force, the second row shows the values of the actions related to the seismic or horizontal ULS combination that that maximizes the moment acting in the plane of the wall M3-3 and the shear force V2 (also acting in the plane of the wall) and that, at the same time, minimizes the axial force N. Following is instead reported the actions at the foot of the walls associated with the different loads considered individually.

Walls

Wall name: Wall ID

N: Total axial force

V2: Shear force (in-plane)

V3: Shear force (out-of-plane)

M2-2: Bending moment (out-of-plane)

M3-3: Bending moment (in-plane)

Wall name	Length [m]	Load / Comb.	N [kN]	V2 [kN]	V3 [kN]	M2-2 [kNm]	M3-3 [kNm]

Capacity design

Dissipative structural behavior

Earthquake-resistant timber buildings should be designed considering either:

- **dissipative structural behaviour;**
- **low-dissipative structural behaviour.**

In the first concept the capability of parts of the structure (dissipative zones) to resist earthquake actions out of their elastic range is taken into account. Dissipative zones shall be located in joints and connections, whereas the timber members themselves shall be regarded as behaving elastically.

In the second concept the action effects are calculated on the basis of an elastic global analysis without taking into account non-linear material behaviour.

Ductility classes

Depending on their ductile behaviour and energy dissipation capacity under seismic actions, buildings shall be assigned to one of the three following ductility classes:

- **DCH, high capacity to dissipate energy;**
- **DCM, medium capacity to dissipate energy;**
- **DCL, low capacity to dissipate energy.**

In DCH and DCM the European standard (UNI EN 1998-1 §8.1.3) requires the use of the capacity design procedure.

The capacity design has the purpose of ensuring a ductile behaviour to the dissipative structure and operates as follows:

- distinguishes elements and mechanisms, both local and global, into ductile and fragile;
- aims to avoid local brittle ruptures and the activation of global brittle or unstable mechanisms;
- aims at locating the energy dissipations by hysteresis in areas of the ductile elements identified and designed for this purpose.

Overstrength factor

To ensure the correct behaviour of the structure, the seismic resistance of the local/global brittle elements/mechanisms must be designed to be grater than that of the ductile elements/mechanisms. To ensure compliance with this inequality, both locally and globally, the strength of the ductile elements/mechanisms is increased by means of a suitable coefficient γ_{Rd} known as the “overstrength factor". Starting from this increased capacity, the capacity of the brittle elements/mechanisms is sized.

Limitation of the stresses to the values determined in the non-dissipative case

The resistance demand evaluated with the capacity design criteria can be assumed not to exceed the strength demand evaluated for the non-dissipative structural behaviour.

Calculation procedure

Applying capacity design locally and globally

The capacity design imposes, as a preliminary step, the definition of which are the dissipative zones and which are the non-dissipative zones. These zones depend on the ductility class adopted and on the structural typology

Planning according to capacity design procedures is therefore divided into two application "levels":

- **local level, related to the connection of the structure;**
- **global level, related to the walls and the building.**

The first has the purpose of avoiding the prevalence of brittle failure modes in dissipative connections. The second instead provides for the application of a series of rules aimed at avoiding non-dissipative collapse mechanisms and fragile breakages of the elements that make up the structure.

Calculation of design resistances

The design strength of the dissipative zones is defined by the following formula:

$$F_{Rd,ductile} = k_{R,deg} \cdot k_{mod} \cdot \frac{F_{Rk,ductile}}{\gamma_M}$$

where:

$F_{Rd,ductile}$ is the design value of the strength of the dissipative zones;

$k_{R,deg}$ is the strength reduction factor due to cyclic degradation;

k_{mod} is the modification factor for duration of load and moisture content;

$F_{Rk,ductile}$ is the characteristic value of the strength of the dissipative zones;

γ_M is the material partial factor.

The design strength of the non-dissipative zones is defined by the following formula:

$$F_{Rd,brittle} = k_{mod} \cdot \frac{F_{Rk,brittle}}{\gamma_M}$$

where:

$F_{Rd,brittle}$ is the design value of the strength of the non-dissipative zones;

k_{mod} is the modification factor for duration of load and moisture content;

$F_{Rk,brittle}$ is the characteristic value of the strength of the non-dissipative zones;

γ_M is the material partial factor.

Check dissipative zones

The dissipative zones against the seismic actions calculated with the dissipative behavior factor need to be verified according to the following expression:

$$F_{Ed,ductile} \leq F_{Rd,ductile} = k_{R,deg} \cdot k_{mod} \cdot \frac{F_{Rk,ductile}}{\gamma_M}$$

where:

$F_{Ed,ductile}$ is the design value of the effect of actions of the dissipative zones;

$F_{Rd,ductile}$ is the design value of the strength of the dissipative zones;

$F_{Rk,ductile}$ is the characteristic value of the strength of the dissipative zones;

$k_{R,deg}$ is the strength reduction factor due to cyclic degradation;

k_{mod} is the modification factor for duration of load and moisture content;

γ_M is the material partial factor.

Check non-dissipative zones – Local level

In order to ensure compliance with the rules of capacity design at the local level (connection), it must be verified that the resistances associated with the brittle failure modes are over-resistant compared to the resistance associated with the ductile failure mode:

$$F_{Rd,brittle} \geq \frac{\gamma_{Rd}}{k_{R,deg}} \cdot F_{Rd,ductile}$$

where:

γ_{Rd} is the overstrength factor;

$k_{R,deg}$ is the resistance degradation coefficient due to cyclic actions;

$F_{Rd,ductile}$ is the design value of the strength of the dissipative zones;

$F_{Rd,brittle}$ is the design value of the strength of the non-dissipative zones.

In other words, the fragile elements of the dissipative connections must be verified for a stress equal to:

$$F_{Ed,brittle} = \frac{\gamma_{Rd}}{k_{R,deg}} \cdot F_{Rd,ductile}$$

where:

γ_{Rd} is the overstrength factor;

$k_{R,deg}$ is the resistance degradation coefficient due to cyclic actions;

$F_{Ed,brittle}$ is the design value of the effect of actions of the non-dissipative zones;

$F_{Rd,ductile}$ is the design value of the strength of the dissipative zones;

Check non-dissipative zones – Global level

The non-dissipative zones need to be checked towards the actions deriving from the application of the capacity design rules. The design effect of the actions is obtained through the following relationship:

$$F_{Ed,brittle} = \Omega \cdot F_{Ed,brittle,E} + F_{Ed,brittle,G}$$

where:

$F_{Ed,brittle}$ is the design action effect in the non-dissipative connection or member;

Ω is the structure overstrength ratio (in both x and y directions);

$F_{Ed,brittle,E}$ is the action effect in the non-dissipative connection or member of the design seismic action;

$F_{Ed,brittle,G}$ is the action effect in the non-dissipative connection or member of the non-seismic actions in the design seismic situation.

Dissipative zones and non-dissipative zones

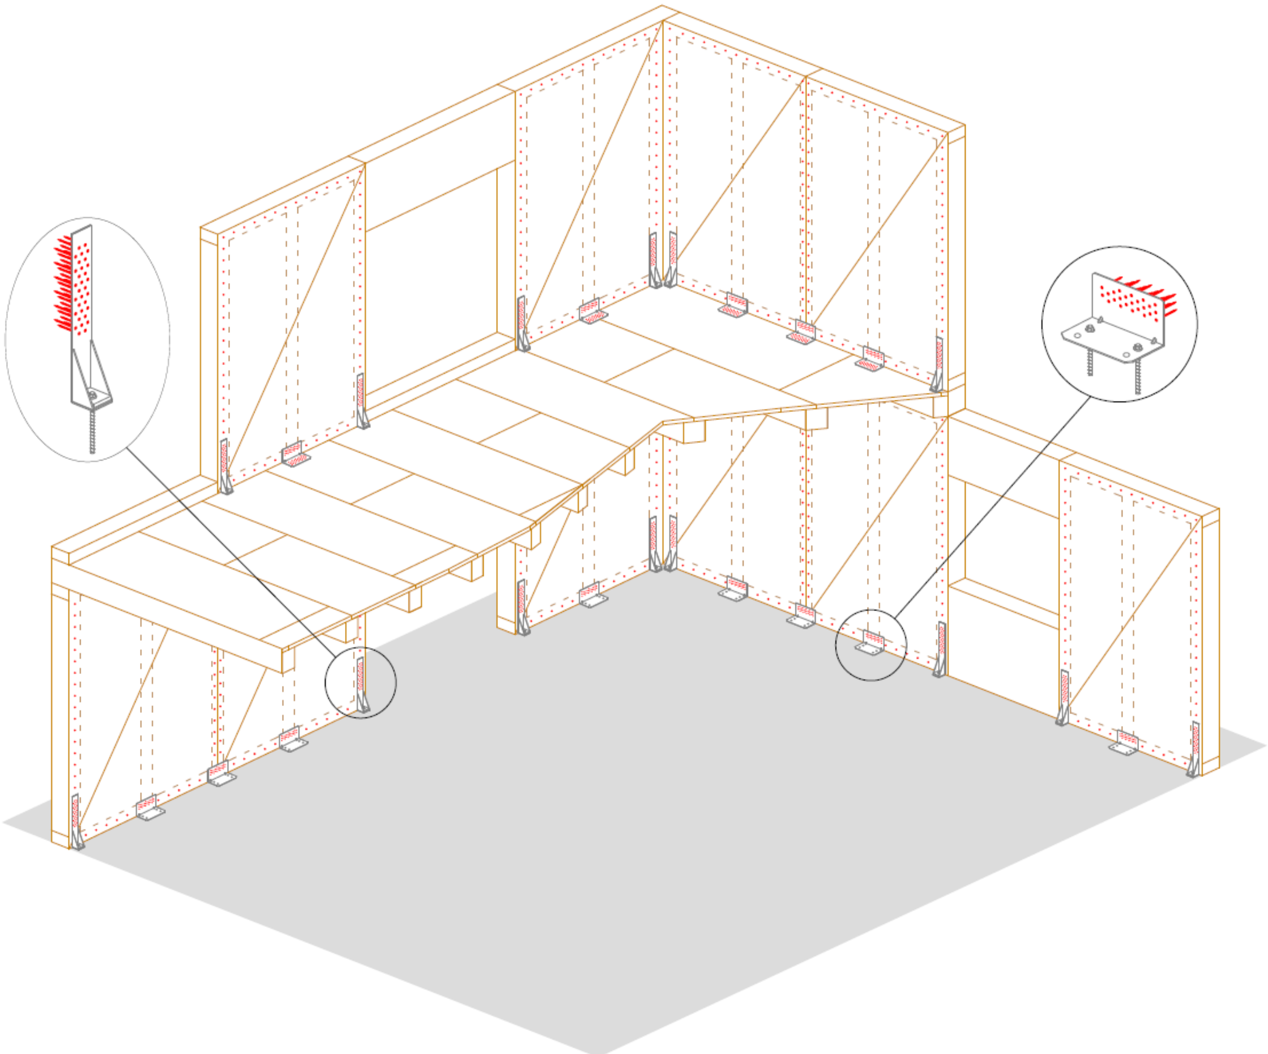
For light frame walls, the dissipative zones consist of:

- mechanical connection between frame and cladding sheets;
- ductile elements of the traction connection (for example the nailing);
- ductile elements of the shear connection (for example the nailing).

The non-dissipative zones are instead represented by:

- cladding sheets;
- brittle elements of the traction connection (for example the concrete anchors);
- brittle elements of the shear connection (for example the concrete anchors);

- timber elements.



Determination of the overstrength ratio

The overstrength ratio for each floor of the building and for each direction is determined by the following expression:

$$\Omega_{i,j} = min\left\{\frac{\sum_{k=1}^{N_{i,j}} V_{Rd,i,j,k}^{sh,CD}}{\sum_{k=1}^{N_{i,j}} \left|V_{Ed,i,j,k}\right|};\frac{\sum_{k=1}^{N_{i,j}} V_{Rd,i,j,k}^{ang,CD}}{\sum_{k=1}^{N_{i,j}} \left|V_{Ed,i,j,k}\right|};\frac{\sum_{k=1}^{N_{i,j}} M_{Rd,i,j,k}^{hd,CD}}{\sum_{k=1}^{N_{i,j}} \left|M_{Ed,i,j,k}\right|}\right\}$$

where:

$\sum_{k=1}^{N_{i,j}} V_{Rd,i,j,k}^{sh,CD}$ is the sum of the design lateral strength related to connections between cladding sheet and timber frame of the j-th shear wall at the i-th storey, taking into account the overstrength factor through the ratio $\gamma_{Rd}/k_{R,deg}$;

$\sum_{k=1}^{N_{i,j}} V_{Rd,i,j,k}^{ang,CD}$ is the sum of the design lateral strength related to shear connections of the j-th shear wall at the i-th storey, taking into account the overstrength factor through the ratio $\gamma_{Rd}/k_{R,deg}$;

$\sum_{k=1}^{N_{i,j}} M_{Rd,i,j,k}^{hd,CD}$ is the sum of the design rocking strength of the j-th shear wall at the i-th storey, taking into account the overstrength factor through the ratio $\gamma_{Rd}/k_{R,deg}$;

$\sum_{k=1}^{N_{i,j}} |V_{Ed,i,j,k}|$ is the sum of the absolute values of the design global shear of the j-th shear wall at the i-th storey due to the seismic action;

$\sum_{k=1}^{N_{i,j}} |M_{Ed,i,j,k}|$ is the sum of the absolute values of the design rocking moment of the jth shear wall at the i-th storey due to the seismic action;

$\boldsymbol{N_{i,j}}$ is the number of shear-walls parallel to the seismic action at the i-th storey.

Overstrength ratios (dynamic analysis)

The following table shows the various contributions that contribute to the determination of the overstrength ratio for the x direction for the various levels of the building.

Diaphragms	Ωx related to the tensile connections	Ωx related to the shear connections	Ωx related to the sheathing panels connections	Ωx related to the jointed CLT connections	Ωx minimum
1	2.00	4.47	3.40	-	2.00
2	3.18	6.73	4.03	-	3.18

Overstrength ratio for the x direction: 2.00

Similarly, the following table shows the various contributions that contribute to the determination of the overstrength ratio for the y direction for the various levels of the building.

Diaphragms	Ωy related to the tensile connections	Ωy related to the shear connections	Ωy related to the sheathing panels connections	Ωy related to the jointed CLT connections	Ωy minimum
1	2.21	4.15	3.14	-	2.21
2	4.66	6.15	3.83	-	3.83

Overstrength ratio for the y direction: 2.21

Limitation of actions to the values determined in the non-dissipative case: Yes

DCL behavior factor q_{DCL} 1.50

Design of the structural elements

Joist floors / solid wood floors

Bending strength

The checks are conducted according to § 6.3.2 of EN 1995-1-1. The following expression shall be satisfied:

$$\frac{\sigma_{m,d}}{k_{crit} \cdot f_{m,d}} \leq 1$$

where:

$\sigma_{m,d}$ is the design bending stress;

$f_{m,d}$ is the design bending strength;

k_{crit} is a factor which takes into account the reduced bending strength due to lateral buckling.

k_{crit} is assumed equal to 1.0 for beams in which the lateral displacement of the compressed edge is prevented over the entire length and the torsional rotation is prevented at the supports.

Shear strength

The checks are conducted according to § 6.1.7 of EN 1995-1-1. The following expression shall be satisfied:

$$\frac{\tau_d}{f_{v,d}} \leq 1$$

where:

τ_d is the design shear stress;

$f_{v,d}$ is the design shear strength for the actual condition.

For the verification of shear resistance of members in bending, the influence of cracks should be taken into account using an effective width of the member given as:

$$b_{ef} = k_{cr} \cdot b$$

where b is the width of the relevant section of the member.

The following value of k_{cr} are used:

k_{cr} = 0.67 (≤1) for solid timber

k_{cr} = 0.67 (≤1) for glued laminated timber

The maximum design shear stress in a rectangular cross section can be evaluated using the following expression:

$$\tau_d = \frac{3}{2} \cdot \frac{V_d}{k_{cr} \cdot A}$$

where A is the area of a joist cross section.

The following table illustrates the structural schemes and the envelopes of the shear force diagram for the joist of each floor with the most sever checks.

Floors deflections (SLS)

The deflection checks are carried out according to § 2.2.3 of EN 1995-1-1.

The net deflection below a straight line between the supports, $w_{net,fin}$, is taken as:

$$w_{net,fin} = w_{inst} + w_{creep} - w_c = w_{fin} - w_c$$

where:

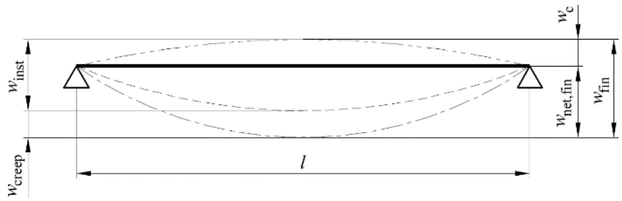
$w_{net,fin}$ is the net final deflection;

w_{inst} is the instantaneous deflection;

w_{creep} is the creep deflection;

w_c is the precamber (if applied);

w_{fin} is the final deflection.



The limiting values for deflections of floors are assumed as shown in the following table.

Deformation limits name	$w_{inst, span}$	$w_{net, fin, span}$	$w_{inst, overhang}$	$w_{net, fin, overhang}$	Neglect overhang check for deformation < 0
Solaio in legno	l/300	l/250	l/150	l/125	No

Instantaneous deflection

The instantaneous deflection w_{inst} is calculated for the characteristic (rare) combination of actions.

The following table shows the deformation of each floor (relative to the element in which the deformation checks are the most severe).

Floor name	Deformation limits name	Combination	Instantaneous deflection
Solaio 12	Solaio in legno	SLS characteristic 3	Solaio 13	Solaio in legno	SLS characteristic 3	
Solaio 20	Solaio in legno	SLS characteristic 8	Solaio 21	Solaio in legno	SLS characteristic 8	Solaio 22	Solaio in legno	SLS characteristic 3	Solaio 23	Solaio in legno	SLS characteristic 3	
The table below shows the instantaneous deflection checks of the floor elements.

Floor name	Section	Combination	Most restrictive check	w_{inst} [mm]	$w_{inst\ limit}$ [mm]	Deflection limit	Check

Final deflection

For structures consisting of members, components and connections with the same creep behaviour and under the assumption of a linear relationship between the actions and the corresponding deformations the final deformation, w_{fin}, may be taken as:

$$w_{fin} = w_{fin,G} + w_{fin,Q1} + \sum w_{fin,Qi}$$

where:

$w_{fin,G} = w_{inst,G} \cdot (1 + k_{def})$ for a permanent action, G

$w_{fin,Q,1} = w_{inst,Q,1} \cdot (1 + \Psi_{2,1} \cdot k_{def})$ for the leading variable action, Q_1

$w_{fin,Q,i} = w_{inst,Q,i} \cdot (\Psi_{0,i} + \Psi_{2,1} \cdot k_{def})$ for accompanying variable actions, Q_i (i>1)

The following table shows the deformation of each floor (relative to the element in which the deformation checks are the most severe).

Floor name	Deformation limits name	Combination	Final deflection

Timber beams

Bending strength

The checks are conducted according to § 6.3.2 of EN 1995-1-1. The following expression shall be satisfied:

$$\frac{\sigma_{m,d}}{k_{crit} \cdot f_{m,d}} \leq 1$$

where:

$\sigma_{m,d}$ is the design bending stress;

$f_{m,d}$ is the design bending strength;

k_{crit} is a factor which takes into account the reduced bending strength due to lateral buckling.

The factor k_{crit} is assumed equal to 1.0 for beams in which the lateral displacement of the compressed edge is prevented over the entire length and the torsional rotation is prevented at the supports. Otherwise, the factor is determined from the following expression:

$$k_{crit} = \begin{cases} 1 & for\ \lambda_{rel,m} \leq 0{,}75 \\ 1{,}56 - 0{,}75\lambda_{rel,m} & for\ 0{,}75 \leq \lambda_{rel,m} \leq 1{,}4 \\ \dfrac{1}{\lambda_{rel,m}^2} & for\ 1{,}4 < \lambda_{rel,m} \end{cases}$$

in which the relative slenderness for bending is taken as:

$$\lambda_{rel,m} = \sqrt{\frac{f_{m,k}}{\sigma_{m,crit}}}$$

and $\sigma_{m,crit}$, the critical bending stress calculated according to the classical theory of stability is taken as:

$$\sigma_{m,crit} = \frac{M_{y,crit}}{W_y} = \frac{\pi\sqrt{E_{0,05}\, I_z\, G_{0,05}\, I_{tor}}}{l_{ef}\, W_y}$$

where:

$E_{0,05}$ is the fifth percentile value of modulus of elasticity parallel to grain;

$G_{0,05}$ is the fifth percentile value of shear modulus parallel to grain;

I_z is the second moment of area about the weak axis z;

I_{tor} is the torsional moment of inertia;

l_{ef} is the effective length of the beam, depending on the support conditions and the load configuration;

W_y is the section modulus about the strong axis y.

The following table shows, for each beam, the bending moment relating to the worst Ultimate Limit State combination.

Shear strength

The checks are conducted according to § 6.1.7 of EN 1995-1-1. The following expression shall be satisfied:

$$\frac{\tau_d}{f_{v,d}} \leq 1$$

where:

τ_d is the design shear stress;

$f_{v,d}$ is the design shear strength for the actual condition.

For the verification of shear resistance of members in bending, the influence of cracks should betaken into account using an effective width of the member given as:

$$b_{ef} = k_{cr} \cdot b$$

where b is the width of the relevant section of the member.

The following value of k_{cr} are used

k_{cr} = 0.67 (≤1) for solid timber

k_{cr} = 0.67 (≤1) for glued laminated timber

The maximum design shear stress in a rectangular cross section can be evaluated using the following expression:

$$\tau_d = \frac{3}{2} \cdot \frac{V_d}{k_{cr} \cdot A}$$

where A is the area of a joist cross section.

The following table illustrates the structural schemes and the envelopes of the shear force diagram for each beam.

Beams deflections (SLS)

The deflection checks are carried out according to § 2.2.3 of EN 1995-1-1.

The net deflection below a straight line between the supports, $w_{net,fin}$, is taken as:

$$w_{net,fin} = w_{inst} + w_{creep} - w_c = w_{fin} - w_c$$

where:

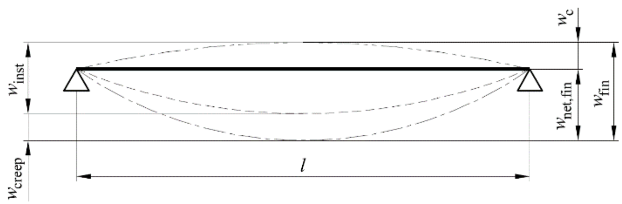
$w_{net,fin}$ is the net final deflection;

w_{inst} is the instantaneous deflection;

w_{creep} is the creep deflection;

w_c is the precamber (if applied);

w_{fin} is the final deflection.



The limiting values for deflections of beams are assumed as shown in the following table.

Deformation limits name	$w_{inst, span}$	$w_{net, fin, span}$	$w_{inst, overhang}$	$w_{net, fin, overhang}$	Neglect overhang check for deformation < 0
Trave in legno	l/300	l/250	l/150	l/125	No

Instantaneous deflection

The instantaneous deflection w_{inst} is calculated for the characteristic (rare) combination of actions.

The following table shows the deformation of each beam.

Beam name	Deformation limits name	Combination	Instantaneous deflection

Final deflection

For structures consisting of members, components and connections with the same creep behaviour and under the assumption of a linear relationship between the actions and the corresponding deformations the final deformation, w_{fin}, may be taken as:

$$w_{fin} = w_{fin,G} + w_{fin,Q1} + \sum w_{fin,Qi}$$

where:

$w_{fin,G} = w_{inst,G} \cdot (1 + k_{def})$ for a permanent action, G

$w_{fin,Q,1} = w_{inst,Q,1} \cdot (1 + \Psi_{2,1} \cdot k_{def})$ for the leading variable action, Q_1

$w_{fin,Q,i} = w_{inst,Q,i} \cdot (\Psi_{0,i} + \Psi_{2,1} \cdot k_{def})$ for accompanying variable actions, Q_i (i>1)

The following table shows the deformation of each floor (relative to the element in which the deformation checks are the most severe).

Timber columns

Stability of columns

The stability of columns subjected to compression is verified in accordance with § 6.3.2 of EN 1995-1-1.

The relative slenderness ratios should be taken as:

$$\lambda_{rel,y} = \frac{\lambda_{,y}}{\pi} \cdot \sqrt{\frac{f_{c,0,k}}{E_{0,05}}}$$

and

$$\lambda_{rel,z} = \frac{\lambda_{,z}}{\pi} \cdot \sqrt{\frac{f_{c,0,k}}{E_{0,05}}}$$

where:

$\lambda_{,y}$ and $\lambda_{rel,y}$ are slenderness ratios corresponding to bending about the y-axis (deflection in the z-direction);

$\lambda_{,z}$ and $\lambda_{rel,z}$ are slenderness ratios corresponding to bending about the z-axis (deflection in the y-direction).

Where both $\lambda_{rel,z} \leq 0{,}3$ and $\lambda_{rel,y} \leq 0{,}3$, the stresses should satisfy the expressions (6.19) and (6.20) in 6.2.4 of EN 1995-1-1.

In all other cases the stresses, which will be increased due to deflection, should satisfy the following expressions:

$$\frac{\sigma_{c,0,d}}{k_{c,y} \cdot f_{c,0,d}} + \frac{\sigma_{m,y,d}}{f_{m,y,d}} + k_m \cdot \frac{\sigma_{m,z,d}}{f_{m,z,d}} \leq 1$$

$$\frac{\sigma_{c,0,d}}{k_{c,z} \cdot f_{c,0,d}} + k_m \cdot \frac{\sigma_{m,y,d}}{f_{m,y,d}} + \frac{\sigma_{m,z,d}}{f_{m,z,d}} \leq 1$$

where the symbols are defined as follows:

$$k_{c,y} = \frac{1}{k_y + \sqrt{k_y^2 - \lambda_{rel,y}^2}}$$

$$k_{c,z} = \frac{1}{k_z + \sqrt{k_z^2 - \lambda_{rel,z}^2}}$$

$$k_y = 0{,}5 \cdot \left(1 + \beta_c \cdot \left(\lambda_{rel,y} - 0{,}3\right) + \lambda_{rel,y}^2\right)$$

$$k_z = 0{,}5 \cdot \left(1 + \beta_c \cdot \left(\lambda_{rel,z} - 0{,}3\right) + \lambda_{rel,z}^2\right)$$

where:

β_c is a factor for members within the straightness limits defined in Section 10 of EN 1995-1-1 and assumes the following values

$$\beta_c = \begin{cases} 0{,}2 \; for \; solid \; timber \\ 0{,}1 \; for \; glued \; laminated \; timber \; and \; LVL \end{cases}$$

The values of the actions in the tables below are related, for each pillar, to the most severe combination of load for the Ultimate Limit State of instability.

Comb.: The most severe combination of load

Dur.: Load duration

N: Axial force

V_2: Shear force along the local axis 2

V_3: Shear force along the local axis 3

M_{2-2}: Bending moment about local axis 2

M_{3-3}: Bending moment about local axis 3

Column name	Comb.	Dur.	N [kN]	V2 [kN]	V3 [kN]	M2-2 [kNm]	M3-3 [kNm]
Pilastro 5	ULS 70	Medium-term	35.49	0.00	0.00	0.00	0.00
Pilastro 6	ULS 70	Medium-term	15.47	0.00	0.00	0.00	0.00
Pilastro 10	ULS 70	Medium-term	36.81	0.00	0.00	0.00	0.00

Pilastro 13	ULS 65	Medium-term	25.63	0.00	0.00	0.00	0.00

The following table summarizes the stability checks for the columns.

Sect.: Column cross section

h: Column height

Area: Cross sectional area of the column

J_y: Area moment of inertia with respect to the y axis

J_z: Area moment of inertia with respect to the z axis

Comb.: The most severe load combination

k_{mod}: Modification factor taking into account the effect of the duration of load and moisture content

γ_M: Partial factor for a material property

$f_{c,0,d}$: Design compressive strength along the grain

$\sigma_{c,0,d}$: Design compressive stress along the grain

Framed walls

Stability of the studs

The stability of the studs subjected to compression is verified in accordance with § 6.3.2 of EN 1995-1-1. Specifically, the checked elements are the internal and the external studs which are the most loaded. These elements (stud or column in a sheathed wall) are braced against buckling in the in-plane direction therefore checks are performed only in the orthogonal direction.

Where both $\lambda_{rel,z}$ ≤0,3 and $\lambda_{rel,y}$ ≤0,3, the stresses should satisfy the expressions (6.19) and (6.20) in 6.2.4 of EN 1995-1-1.

In all other cases the stresses, which will be increased due to deflection, should satisfy the following expression:

$$\frac{\sigma_{c,0,d}}{k_c \cdot f_{c,0,d}} + \frac{\sigma_{m,y,d}}{f_{m,y,d}} \leq 1$$

The values of the actions in the tables below are related, for each pillar, to the most severe combination of load for the Ultimate Limit State of instability.

The following table summarizes the stability checks for the studs of the framed walls.

Section: Type of cross-section of the stud

h_{stud}: Stud height

A_{stud}: Cross sectional area of the stud

J_{stud}: Cross sectional moment of inertia of the stud

Comb.: The most severe load combination

k_{mod}: Modification factor taking into account the effect of the duration of load and moisture content

γ_M: Partial factor for a material property

$f_{c,0,k}$: Characteristic compressive strength along the grain

$f_{m,k}$: Design bending strength

$\sigma_{c,0,d}$: Design compressive stress along the grain

$\sigma_{m,d}$: Design bending stress about the principal axis

Wall name	Section	Stud	h_{stud} [m]	A_{stud} [mm^2]	J_{stud} [mm^4]	kc_{stud}	Comb.	Service Class	k_{mod}	γ_M	$f_{c,0,k}$	$f_{m,k}$	N [kN]	$\sigma_{c,0,d}$ [MPa]	$\sigma_{m,d}$ [MPa]	Check

Compression perpendicular to the grain

The studs are supported at the base by the bottom plate which is stressed by compression forces perpendicular to the grain.

The following expression shall be satisfied:

$$\sigma_{c,90,d} \leq k_{c,90,d} \cdot f_{c,90,d}$$

with

$$\sigma_{c,90,d} = \frac{F_{c,90,d}}{A_{ef}}$$

where:

$\sigma_{c,90,d}$ is the design compressive stress in the effective contact area perpendicular to the grain;

$F_{c,90,d}$ is the design compressive load perpendicular to the grain;

A_{ef} is the effective contact area in compression perpendicular to the grain;

$f_{c,90,d}$ is the design compressive strength perpendicular to the grain;

$k_{c,90,d}$ is a factor taking into account the load configuration, the possibility of splitting and the degree of compressive deformation.

The effective contact area perpendicular to the grain, A_{ef}, should be determined taking into account an effective contact length parallel to the grain, where the actual contact length, l, at each side is increased by 30 mm, but not more than a, l or l1/2, see Figure 6.2 of EN 1995-1-1.

The value of $k_{c,90}$ should be taken as 1,0 unless the conditions in the following paragraphs apply. For members on continuous supports, provided that $l_1 \geq 2h$ (see Figure 6.2a of EN 1995-1-1), the value of $k_{c,90}$ should be taken as:

$k_{c,90}$ = 1,25 for solid softwood timber

$k_{c,90}$ = 1,5 for glued laminated softwood timber

where h is the depth of the member and l is the contact length.

The values of the actions in the tables below are related, for each wall, to the most severe combination of load for the compression Ultimate Limit State.

Wall name	Length [m]	Comb.	Dur.	N [kN]

The following table summarizes the compression (perpendicular to the grain) checks for plates of the framed walls.

Wall name: Wall ID

A_{eff}: Effective contact area in compression perpendicular to the grain of the bottom plate

$k_{c,90}$: Factor taking into account the load configuration, the possibility of splitting and the degree of compressive deformation

Comb.: The most severe combination

k_{mod}: Modification factor taking into account the effect of the duration of load and moisture content

γ_M: Partial factor for a material property

$f_{c,90,k}$: Characteristic compressive strength perpendicular to grain

$\sigma_{c,90,d}$: Design compressive stress perpendicular to grain

Wall name	Section	Stud	A_{eff} [mm^2]	$k_{c,90}$	Comb.	Service class	k_{mod}	γ_M	$f_{c,90,k}$ [MPa]	N [kN]	$\sigma_{c,90,d}$ [MPa]	Check

Shear (load in-plane)

The values of the actions in the tables below are related, for each wall, to the most severe combination of load for the Ultimate Limit State.

In the case of seismic combinations, the overstrength ratio Ω, the shear forces $V2^{CD}$ evaluated in accordance with the rules of capacity design and the shear forces $V2^{ND}$ determined in the case of non-dissipative structural behavior are also reported.

Wall name	Length [m]	Comb.	Dur.	V2 [kN]	Ω	$V2^{CD}$ [kN]	Limitation to the non-dissipative value	$V2^{ND}$ [kN]

The verifications are carried out against the shear forces V2. If the most severe load combination is of the seismic type, the checks on the sheathing panels are carried out against the $V2^{CD}$ shear forces, possibly limited to $V2^{ND}$ values.

Lateral load-carrying capacity of metal fasteners

The design load-carrying capacity of a cantilevered panel secured against uplift is determined using the simplified method of analysis for walls proposed by EN 1995-1-1 9.2.4.2 “Simplified analysis of wall diaphragms – Method A”.

For a wall made up of several wall panels, the design racking load-carrying capacity of a wall should be calculated from:

$$F_{v,Rd} = \sum_i F_{i,v,Rd}$$

where:

$F_{i,v,Rd}$ is the design racking load-carrying capacity of the wall panel in accordance with 9.2.4.2(3) and 9.2.4.2(5) of EN 1995-1-1.

Wall panels which contain a door or window opening should not be considered to contribute to the racking load-carrying capacity.

The design racking load-carrying capacity of each wall panel, $F_{i,v,Rd}$, should be calculated from:

$$F_{i,v,Rd} = \frac{F_{t,Rd} \cdot b_i \cdot c_i}{s}$$

where:

$F_{t,Rd}$ is the lateral design capacity of an individual fastener, modified by a factor of 1.2 in accordance with clause 9.2.4.2 (5);

b_i is the wall panel width;

s is the fastener spacing;

c_i a coefficient dependent on the ratio between base and height of a single wall panel.

For wall panels with sheets on both sides the following rules apply:

- if the sheets and fasteners are of the same type and dimension then the total racking load carrying capacity of the wall should be taken as the sum of the racking load-carrying capacities of the individual sides;
- if different types of sheets are used, 75 % of the racking load-carrying capacity of the weaker side may, unless some other value is shown to be valid, be taken into consideration if fasteners with similar slip moduli are used. In other cases not more than 50 % should be taken into consideration.

Connector strength

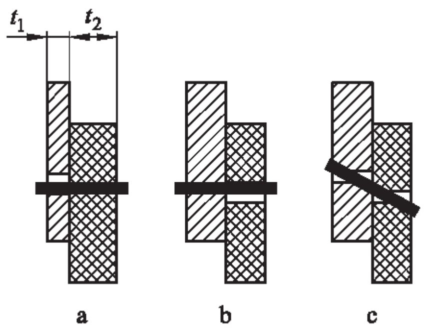
The resistance of each connector is estimated according to the theory of Johansen presented in 8.2.2 EN 1995-1-1 for panel-to-timber connections (Single shear).

The characteristic load-carrying capacity for nails, staples, bolts, dowels and screws per shear plane per fastener, should be taken as the minimum value found from the following expressions

$$F_{v,Rk,a} = f_{h,1,k} \cdot t_1 \cdot d$$

$$F_{v,Rk,b} = f_{h,2,k} \cdot t_2 \cdot d$$

$$F_{v,Rk,c} = \frac{f_{h,1,k} \cdot t_1 \cdot d}{1+\beta} \cdot \left[\sqrt{\beta + 2\beta^2\left[1+\frac{t_2}{t_1}+\left(\frac{t_2}{t_1}\right)^2\right] + \beta^3\left(\frac{t_2}{t_1}\right)^2} - \beta\left(1+\frac{t_2}{t_1}\right)\right] + \frac{F_{ax,Rk}}{4}$$



$$F_{v,Rk,d} = 1{,}05 \cdot \frac{f_{h,1,k} \cdot t_1 \cdot d}{2+\beta} \cdot \left[\sqrt{2\beta(1+\beta) + \frac{4\beta(2+\beta)M_{y,Rk}}{f_{h,1,k} \cdot d \cdot t_1^2}} - \beta\right] + \frac{F_{ax,Rk}}{4}$$

$$F_{v,Rk,e} = 1{,}05 \cdot \frac{f_{h,1,k} \cdot t_2 \cdot d}{1+2\beta} \cdot \left[\sqrt{2\beta^2(1+\beta) + \frac{4\beta(1+2\beta)M_{y,Rk}}{f_{h,1,k} \cdot d \cdot t_2^2}} - \beta\right] + \frac{F_{ax,Rk}}{4}$$

$$F_{v,Rk,f} = 1{,}15 \cdot \sqrt{\frac{2\beta}{1+\beta}}\sqrt{2 \cdot M_{y,Rk} \cdot f_{h,1,k} \cdot d} + \frac{F_{ax,Rk}}{4}$$

In the expressions above, the first term on the right hand side is the load-carrying capacity according to the Johansen yield theory, whilst the second term $\frac{F_{ax,Rk}}{4}$ is the contribution from the rope effect.

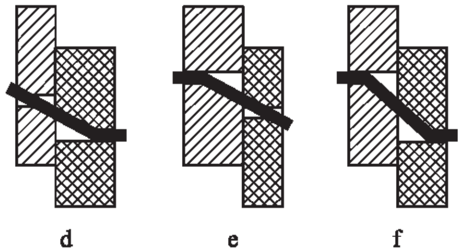


Figure: Failure modes for timber and panel connections.

Characteristic withdrawal capacity

The characteristic withdrawal capacity of nails, $F_{ax,Rk}$, should be taken as the smaller of the values found from the following expressions:

- For smooth nails:

$$F_{ax,Rk} = \begin{cases} f_{ax,k,tip}\, d\, t_{pen,frame} \\ f_{ax,k,head}\, d\, t + f_{head,k}\, d_h^2 \end{cases}$$

- For nails with improved adherence:

$$F_{ax,Rk} = \begin{cases} f_{ax,k,tip}\, d\, t_{pen,frame} = f_{ax,k,350} \left(\frac{\rho_{k,tip}}{350}\right)^{0.8} d\, t_{pen,frame} \\ f_{head,k}\, d_h^2 = f_{head,k,350} \left(\frac{\rho_{k,head}}{350}\right)^{0.8} d_h^2 \end{cases}$$

where:

$f_{ax,k,tip}$ is the characteristic pointside withdrawal strength;

$f_{ax,k,head}$ is the characteristic headside withdrawal strength;

$f_{head,k}$ is the characteristic headside pull-through strength;

d is the nail diameter;

d_h is the nail head diameter;

$t_{pen,frame}$ is the minimum value between the pointside penetration length and the length of the threaded part in the pointside member;

t is the thickness of the headside member.

In accordance with 8.3.2 (7) for smooth nails, the pointside penetration should be at least 8d. For nails with a pointside penetration smaller than 12d the withdrawal capacity should be multiplied by $\frac{t_{pen}}{4d} - 2$.

For threaded nails, the pointside penetration should be at least 6d. For nails with a pointside penetration smaller than 8d the withdrawal capacity should be multiplied by $\frac{t_{pen}}{2d} - 3$.

In the following table are reported the calculations for the characteristic pointside withdrawal strength ($F_{ax,k,tip}$) and for the characteristic headside pull-through strength ($F_{ax,k,head}$).

Lateral load-carrying capacity

The following table shows the resistances of the fasteners used to assemble the panels of the walls.

$F_{ax,Rk}$ is the characteristic axial withdrawal capacity of the fastener

Rope effect limit is the rope effect limited to a percentage of Johansen part

$F_{v,Rk}$ is the characteristic load-carrying capacity per shear plane per fastener

Check of the bearing capacity of the walls related to the lateral load-carrying capacity of metal fasteners

The following table summarizes the geometric characteristics of the wall panels and their load-bearing capacity $F_{i,v,Rk}$. This table also indicates whether the panels fulfill the geometrical requirements of 9.2.4.2(2) EN 1995-*1-1:*

- the spacing of fasteners is constant along the perimeter of every sheet;
- the width of each sheet is at least h/4.

The following table instead shows checks with reference to the most significant load combinations.

Where a connection is constituted of two timber elements having different time-dependent behaviour, the calculation of the design load-carrying capacity should be made with the following modification factor $k_{mod,conn,i}$:

$$k_{mod,conn,i} = \sqrt{k_{mod,studs} \cdot k_{mod,side\ i}}$$

Wall name	Section	Comb.	Service class	Dur.	k_{mod} studs	k_{mod1}	k_{mod2}	$k_{R,deg}$	γ_M	$F_{v,Rd}$ [kN]	$F_{v,Ed}$ [kN]	Check

Shear strength of the sheeting boards

The design load-carrying capacity of a cantilevered panel secured against uplift is determined using the simplified method of analysis for walls proposed by EN 1995-1-1 9.2.4.2 “Simplified analysis of wall diaphragms – Method A”.

For a wall made up of several wall panels, the design racking load-carrying capacity of a wall should be calculated from:

$$F_{v,Rd} = \sum_i F_{i,v,Rd}$$

where:

$F_{i,v,Rd}$ is the design racking load-carrying capacity of the wall panel in accordance with 9.2.4.2(3) and 9.2.4.2(5) of EN 1995-1-1.

The load-carrying capacity of a sheeting panel $F_{i,v,Rd}$ is:

$$F_{i,j,v,Rd} = f_{j,v,d} \cdot b_i \cdot t_{i,j}$$

where

$F_{i,j,v,Rd}$ is the shear strength of the single sheet, in which the first subscript indicates the panel of belonging and the second the side, external or internal;

$f_{j,v,d}$ is the shear strength of the single sheeting board;

b_i is the panel width;

$t_{i,j}$ is the thickness of the sheeting board.

The following table summarizes the load-bearing capacity $F_{i,v,Rk}$ of the wall panels. This table also indicates whether the panels fulfil the geometrical requirements of 9.2.4.2(2) EN 1995-1-1.

Wall name	Section	Panel	b_i [mm]	t_i side 1 [mm]	$f_{v,k}$ side 1 [MPa]	t_i side 2 [mm]	$f_{v,k}$ side 2 [MPa]	N of panels	Geometric check EN 1995-1-1 9.2.4.2 (2)	$F_{i,v,Rk}$ side 1 [kN]	$F_{i,v,Rk}$ side 2 [kN]

Shear buckling of the sheet

According to 9.2.4.2 of EN 1995-1-1 shear buckling of the sheet may be disregarded, provided that

$$\frac{b_{net}}{t} \leq 100$$

where:

b_{net} is the clear distance between studs;

t is the thickness of the sheet.

Connections

Hold down – Connection at the base of the structure

The design resistance R_d of the hold-downs is determined as the minimum value among the resistances relating to the following failure modes:

- nailing failure;
- hold-downs steel failure;
- failure of the concrete anchors.

Tensile force

The tensile force acting on the hold down (T_a) is evaluated as described in paragraph "Model Description".

The tensile force acting on the concrete anchors is calculated taking into account the additional moment due to the non-alignment between the external force acting on the vertical flange of the hold down and the anchors themselves using a coefficient, indicated as k_t.

$$T_p = T_a \cdot k_t$$

Nailing resistance

The design value of the load-bearing capacity of the nailing is given by the following expression

$$R_{c,d} = \frac{k_{mod} \cdot R_{c,k,dens}}{\gamma_M}$$

where:

$R_{c,k,dens}$ is the characteristic value of the nailing resistance. This value is reduced by the k_{dens} factor when the density of the material used is less than 350 kg/m^3. k_{dens} can be evaluated using the formula $R_{c,k,dens} = R_{c,k} \cdot \left(\frac{\rho_k}{350}\right)^2$;

k_{mod} is the modification factor taking into account the effect of the duration of load and moisture content;

γ_M is the is the partial factor for the connections.

Steel resistance

The tensile design strength of the hold-down can be evaluated according to the formula

$$R_{s,d} = \frac{R_{s,k}}{\gamma_{M2}}$$

where:

$R_{s,k}$ is the characteristic value of the resistance of the hold-down;

γ_{M2} is the partial factor for resistance of cross-sections in tension to fracture.

Concrete anchors resistance

The tension resistance of the concrete anchors can be evaluated according to the formula

$$R_{p,d} = \frac{R_{p,k}}{\gamma}$$

where:

$R_{p,k}$ is the characteristic value of the resistance of the concrete anchors;

γ is the safety factor.

The checks are summarized in the following table which shows the characteristic values of the resistances associated with collapse of the various components.

Name: Name of the connection in which the hold-down is used

Comb.: The most severe combination of load

$T_{a,d}$: Design value of the tensile force acting on the hold down

$T_{p,d}$: Design value of the tensile force acting on the concrete anchors

k_{mod}: Modification factor taking into account the effect of the duration of load and moisture content

$k_{R,deg}$: Resistance degradation coefficient due to cyclic actions

γ_M: Partial safety factor

$R_{a,d}$: Design value of the hold down resistance, assumed to be the lower of the values of the design resistance of all the failure mechanisms associated with it

$R_{p,d}$: Design value of the concrete anchors resistance

$$T_{a,d} \leq R_{a,d} = min(R_{c,d}; R_{s,d})$$

$$T_{p,d} \leq R_{p,d}$$

Capacity design: local level

In order to ensure compliance with the rules of capacity design at the local level (connection), it must be verified that the resistances associated with the brittle failure modes are over-resistant compared to the resistance associated with the ductile failure mode.

$$R_{brittle,d} \geq \frac{\gamma_{Rd}}{k_{R,deg}} \cdot R_{ductile,d}$$

The checks on the over-resistance of the brittle failure modes are summarized in percentage form in the following table.

Wall name	Connection name	$R_{c,d}$ [kN]	$R_{s,d}$ [kN]	$R_{p,d}$ [kN]	Ductile failure	$k_{R,deg}$	γ_{Rd}	Local capacity design verification: nailing	Local capacity design verification: steel connection element	Local capacity design verification: anchors

Timber to timber tensile plate – Upper levels connection

The design resistance R_d of a punched strap is determined as the minimum value among the resistances relating to the following failure modes:

- nailing failure;
- punched strap steel failure.

Tensile force

The tensile force acting on the punched metal plate (T_a) is evaluated as described in paragraph “Model Description”.

Wall name	Length [m]	Connection name	N° of connections at each wall end	Comb.	Dur.	N [kN]	M_{3-3} [kNm]	Ta [kN]

Steel resistance

The tensile resistance of the punched element is evaluated on the basis of the indications of 6.2.3 EN 1993-1-1. For sections with holes the design tension resistance $N_{t,Rd}$ should be taken as the smaller of the design plastic resistance of the gross cross-section and the design ultimate resistance of the net cross-section at holes for fasteners.

The design plastic resistance of the gross cross-section is calculated as

$$R_{pl,Rd} = \frac{A \cdot f_y}{\gamma_{M0}}$$

where:

A is the area of the gross cross-section;

f_y is the nominal values of the yield strength of steel;

γ_{M0} is the partial factor for resistance of cross-sections.

The net cross section resistance can be evaluated using the following expression:

$$R_{u,Rd} = \frac{0.9 \cdot A_{net} \cdot f_u}{\gamma_{M2}}$$

where:

A_{net} is the cross sectional net area;

f_u is the ultimate strength of the yield strength of steel;

γ_{M2} is the partial factor for resistance of cross-sections in tension to fracture.

Nailing resistance

The characteristic resistance of the connection was calculated as the product between the effective number of fasteners inserted and bearing capacity of the single fastener

$$R_{c,k} = n_{ef} \cdot R_{k,conn}$$

where the bearing capacity of the single fastener $R_{conn,k}$ is evaluated using Johansen theory and the effective number of fasteners is evaluated in accordance with 8.3.1.1 (8) and 8.5.1.1 (4) – EN 1995-1-1.

The design value of the load-bearing capacity is given by

$$R_{c,d} = \frac{k_{mod} \cdot R_{c,k}}{\gamma_M}$$

where:

$R_{c,k}$ is the characteristic resistance of the fastener;

k_{mod} is the modification factor taking into account the effect of the duration of load and moisture content;

γ_M is the partial factor for connections.

The checks are summarized in the following table which shows the characteristic values of resistance associated with the different failure modes of the components.

Name: Name of the connection in which the punched strap is used

Comb.: The most severe combination of load

$T_{a,d}$: Design force acting on the connection

k_{mod}: Modification factor taking into account the effect of the duration of load and moisture content

$k_{R,deg}$: Resistance degradation coefficient due to cyclic actions

γ_M: Partial safety factor

R_d: Design value of the resistance, assumed to be the lower of the values of the design resistance of all the failure mechanisms considered

$$T_{a,d} \leq min(R_{pl,Rd};\ R_{u,d};\ R_{c,d})$$

Timber to concrete angle bracket – Connection at the base of the structure

The design resistance R_d of an angle bracket is determined as the minimum value among the resistances relating to the following failure modes:

- shear failure of the angle and/or of the group of fasteners of the connection;
- shear failure of the anchors connecting the concrete.

Shear force

The shear force acting on the single angle bracket is calculated by dividing the total shear force V_2 by the number of angle brackets present in the wall (taking into account the possible presence of angle brackets on both sides of the structural element).

$$V_a = \frac{V_2}{n_{anc}}$$

where:

V_2 is the design shear force on the considered wall;

n_{anc} is the number of shear connections present in the wall.

The shear force acting on the concrete anchors of each angle bracket is equal to V_a.

Wall name	Length [m]	Connection name	N of connections	Comb.	Dur.	V_2 [kN]	Va [kN]

Angle bracket resistance

The design value of the shear bearing capacity of the angle bracket can be estimated from the characteristic value by means of the following expression

$$R_{a,d} = \frac{k_{mod} \cdot R_{a,k,dens}}{\gamma_M}$$

where:

$R_{a,k,dens}$ is the characteristic value of the nailing resistance. This value is reduced by the k_{dens} factor when the density of the material used is less than 350 kg/m^3. k_{dens} can be evaluated using the formula $R_{a,k,dens} = R_{a,k} \cdot \left(\frac{\rho_k}{350}\right)^2$.

Concrete anchors resistance

The shear resistance of the concrete anchors is evaluated by the following formula

$$R_{p,d} = \frac{R_{p,k}}{\gamma}$$

where:

$R_{p,k}$ is the characteristic value of the shear resistance of the concrete anchors;

γ is the safety factor.

The checks are summarized in the following table which illustrates the characteristic values of the resistances associated to the different components and their design values.

Name: Name of the connection in which the angle bracket is used

Comb.: The most severe combination of load

$V_{a,d}$: Shear force acting on the angle bracket and on the concrete anchors

k_{mod}: Modification factor taking into account the effect of the duration of load and moisture content

$k_{R,deg}$: Resistance degradation coefficient due to cyclic actions

γ_M: Partial safety factor

$R_{a,d}$: Design value of the angle bracket resistance

$R_{p,d}$: Design value of the concrete anchors resistance

$$V_{a,d} \leq R_{a,d}$$

$$V_{a,d} \leq R_{p,d}$$

Capacity design: local level

In order to ensure compliance with the rules of capacity design at the local level (connection), it must be verified that the resistances associated with the brittle failure modes are over-resistant compared to the resistance associated with the ductile failure mode.

$$R_{brittle,d} \geq \frac{\gamma_{Rd}}{k_{R,deg}} \cdot R_{ductile,d}$$

The checks on the over-resistance of the brittle failure modes are summarized in percentage form in the following table.

Wall name	Connection name	$R_{a,d}$ [kN]	$R_{p,d}$ [kN]	Ductile failure	$k_{R,deg}$	γ_{Rd}	Local capacity design verification: anchors

Timber to timber angle bracket

The design resistance R_d of an angle bracket is determined as the resistance of the following failure mode:

- shear failure of the angle and/or of the group of fasteners of the connection.

Shear force

The shear force acting on the single angle bracket is calculated by dividing the total shear force V_2 by the number of angle brackets present in the wall (taking into account the possible presence of angle brackets on both sides of the structural element).

$$V_a = \frac{V_2}{n_{anc}}$$

where:

V_2 is the design shear force on the considered wall;

n_{anc} is the number of shear connections present in the wall.

Angle bracket resistance

The design value of the shear strength of the anchor is evaluated as

$$R_{a,d} = \frac{k_{mod} \cdot R_{a,k,dens}}{\gamma_M}$$

where:

$R_{a,k,dens}$ is the characteristic value of the nailing resistance. This value is reduced by the k_{dens} factor when the density of the material used is less than 350 kg/m^3. k_{dens} can be evaluated using the formula $R_{a,k,dens} = R_{a,k} \cdot \left(\frac{\rho_k}{350}\right)^2$;

k_{mod} is the modification factor taking into account the effect of the duration of load and moisture content;

γ_M is the partial factor for connections.

The checks are summarized in the following table which illustrates the characteristic values of the resistance associated to the angle brackets and their design values. The following expression shall be satisfied:

$$V_{a,d} \leq R_{a,d}$$

Name: Name of the connection in which the angle bracket is used

Comb.: The most severe combination of load

$V_{a,d}$: Design value of the force acting on the single angular

k_{mod}: Modification factor taking into account the effect of the duration of load and moisture content

$k_{R,deg}$: Resistance degradation coefficient due to cyclic actions

γ_M: Partial safety factor

Damage Limitation - DLS

The “damage limitation requirement” is considered to have been satisfied, if, under a seismic action having a larger probability of occurrence than the design seismic action corresponding to the “no-collapse requirement” the interstorey drifts are limited in accordance with the following equation:

$$d_r < d_{\mathrm{r,lim}} = 0.005\ \mathrm{h}$$

where:

d_r is the interstorey drift obtained applying the reduction factor ν = 0.5 to the design ground acceleration a_g on type A ground;

h is the storey height.

The table below shows the seismic checks for the Damage Limit State.

Wall name: Wall ID

h: Storey height

Comb.: The most severe combination of load

d_r: Evaluated interstorey drift

$d_{r,lim}$: Interstorey drift limit

The table provides the Damage Limit State checks in the case of Dynamic Linear Analysis.
